Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

Summary

During the reporting period the following work was carried out on Jubilee Mines NL's Kathleen Valley tenure:

- **Soil Sampling- Mercury- M36/349, 371-** 620 Samples were collected which generated 5 nickel related anomalies.
- **Soil Sampling-Vanguard-M36/24-** A total of 446 soil samples were collected, no nickel anomalies were defined however two gold-in-soil anomalies were confirmed over areas which have been extensively drilled historically to exploit the gold mineralisation, confirming the veracity of the technique.
- **Rock Chip Sampling- M36/24, 349, 371-** A total of 32 rock chip samples were collected as part of field reconnaissance of soil anomalies.
- **Geological Review of Pegmatites**
- **Geological Review Copper within Layered Gabbro.**
- **Resource Modelling at Mossbecker** defined non JORC compliant resources of some ***1.05mt @ 2.29g/t Au for 77270 oz of gold.***
- **Resource modelling at Yellow Aster** defined non JORC compliant resources of some ***2.298mt @ 1.44g/t Au for 106385 oz of gold.***
- **RC Drilling** for 66 holes, 6655m and 5269 laboratory assay samples was completed at the following prospects:

Five Creek: FCC029-38 which failed to define Ni anomalism.

Ilias: IRC014-20, produced only low level gold anomalism

Cosmos West: JVC025-26, holes were stopped before target depth and require re-drilling.

North Carriport: NCRC001-29 produced low level gold mineralisation with a best intercept of ***1m @ 4.5g/t Au from 51m in NCRC018.***

South Yellow Aster: SYRC001-2 produced low level gold anomalism.

Vanguard South: VSRC1-16, were drilled for geotechnical and water monitoring purposes.

- **Diamond Drilling:** A total of 3 geotechnical holes, VSD002-5 were drilled at Vanguard for 335.6m and 13 laboratory assay samples. VSD005 intercepted VMS style mineralisation with a best intercept of:
0.43m @ 9% Zn, 985ppm Cu, 5.67% Pb and 176ppb Au from 182.12m
- **Cosmos Deep UnderGround Diamond Drilling** was completed for 41 holes, for 7872.32m and 2316 Laboratory assay samples in holes CDE029-33, 037, 049-58, CME073-92, ISD159-163. A number of significant Ni intercepts were encountered:

CME077 0.9m@ 7.02% Ni

Inc 1m @13.40%Ni

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

CME079	3.3m @6.83%Ni <i>Inc 0.85m @ 12.54%Ni</i>
CME083	4.53m @4.07% Ni <i>Inc 0.43m @18.3% Ni</i>

- **Moving Loop EM Survey** was completed at Mercury-Venus-M36/371, for 23 lines, 27.81 line km and 583 stations. Previously defined surface EM conductors C₈-C₁₁ were confirmed, one new conductor was defined at ~259050mE/6945700mN which may represent a possible VMS target.
- **Geoferret Moving Loop Survey-BHP Billiton-M36/377-** A total of 15 lines of MLEM survey were completed on Jubilee's ground as part of BHPB's survey of their ground east of M36/377. No anomalies were defined within the data supplied to Jubilee.
- **DHEM Surveys-** DHEM was completed on geotechnical hole VSD005 and on 25 underground holes, CME073, 75-76, 78-79, 83-92, CDE049-57, ISD160. A number of conductors were defined.
- **Physical Property Testing** a total of 12 samples from Cosmos, Cosmos Deep and Five Creek diamond drill holes (drilled in previous period) were tested for their physical properties to assist with interpretation of geophysical datasets.
- **Mining:** During 2005 mining at Cosmos Deep produced 195 925tonnes of ore at a grade of 5.5% Ni. A total of 52 925 dry metric tonnes of ore were shipped from the port of Esperance to Inco in Canada in 7 shipments.
- **Resource Modelling at Cosmos Deep**s produced a resource of 319 000tonnes at 7.6% Ni for 24 210tonnes of contained Ni and a reserve of 307 000tonnes at 5.7% Ni for 17 500 tonnes of contained Ni.

Conclusion

- Diamond drilling at Vanguard defined a potential VMS target that requires follow up.
- Soil sampling at Mercury produced a number of Nickel targets worthy of follow up.
- Cosmos West RC drilling requires completion.
- The ore positions north and south of both Cosmos and Cosmos Deep deposits remain poorly understood and high priority target areas. A multi disciplinary evaluation approach utilising pathfinder geochemistry, geophysics, shallow air-core Lithogeochemical drilling, depth target and stratigraphic RC and diamond drilling. Volcanogenic and structural analysis should be continued with the aim of delineating additional resources which would be easily exploitable via existing mine infrastructure.

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

1 Introduction

Sir Samuel Mines NL (ACN 009 173 906), a wholly owned subsidiary of Jubilee Mines NL (ACN 009 219 809), operates the Kathleen Valley Project, which comprises two blocks of tenements. One block comprises the 100% owned ground, which is the subject of this report the other is operated as a joint venture with Giralia Resources NL and which is reported under separate cover as the Kathleen Valley Joint Venture.

Jubilee has been active in this area since 1987. Much of the exploration since that time concentrated on gold mineralisation centred around the historic gold workings of Carriport, Mossbecker, Yellow Aster and Nils Desperandum. However during 1997 Jubilee focused its attention on the nickel potential of the tenure resulting in the discovery of the Cosmos massive nickel sulphide deposit on M36/371.

In early 2000 Jubilee discovered a second nickel sulphide deposit some 300-400m below the now exhausted Cosmos open pit. Open Pit mining of the Cosmos Open Pit ceased during 2003 whilst underground mining of the Cosmos Deep commences during the same period. Much of the work during 2005 involved underground drilling to test conceptual Ni sulphide (\$) targets at depth below the Cosmos Deep deposit. Further work continued to the north of Cosmos to characterise the continuity of the Cosmos Ultramafic and to drill test the continuity of gold mineralisation associated with the Jones Creek Conglomerates.

1.1 Tenure

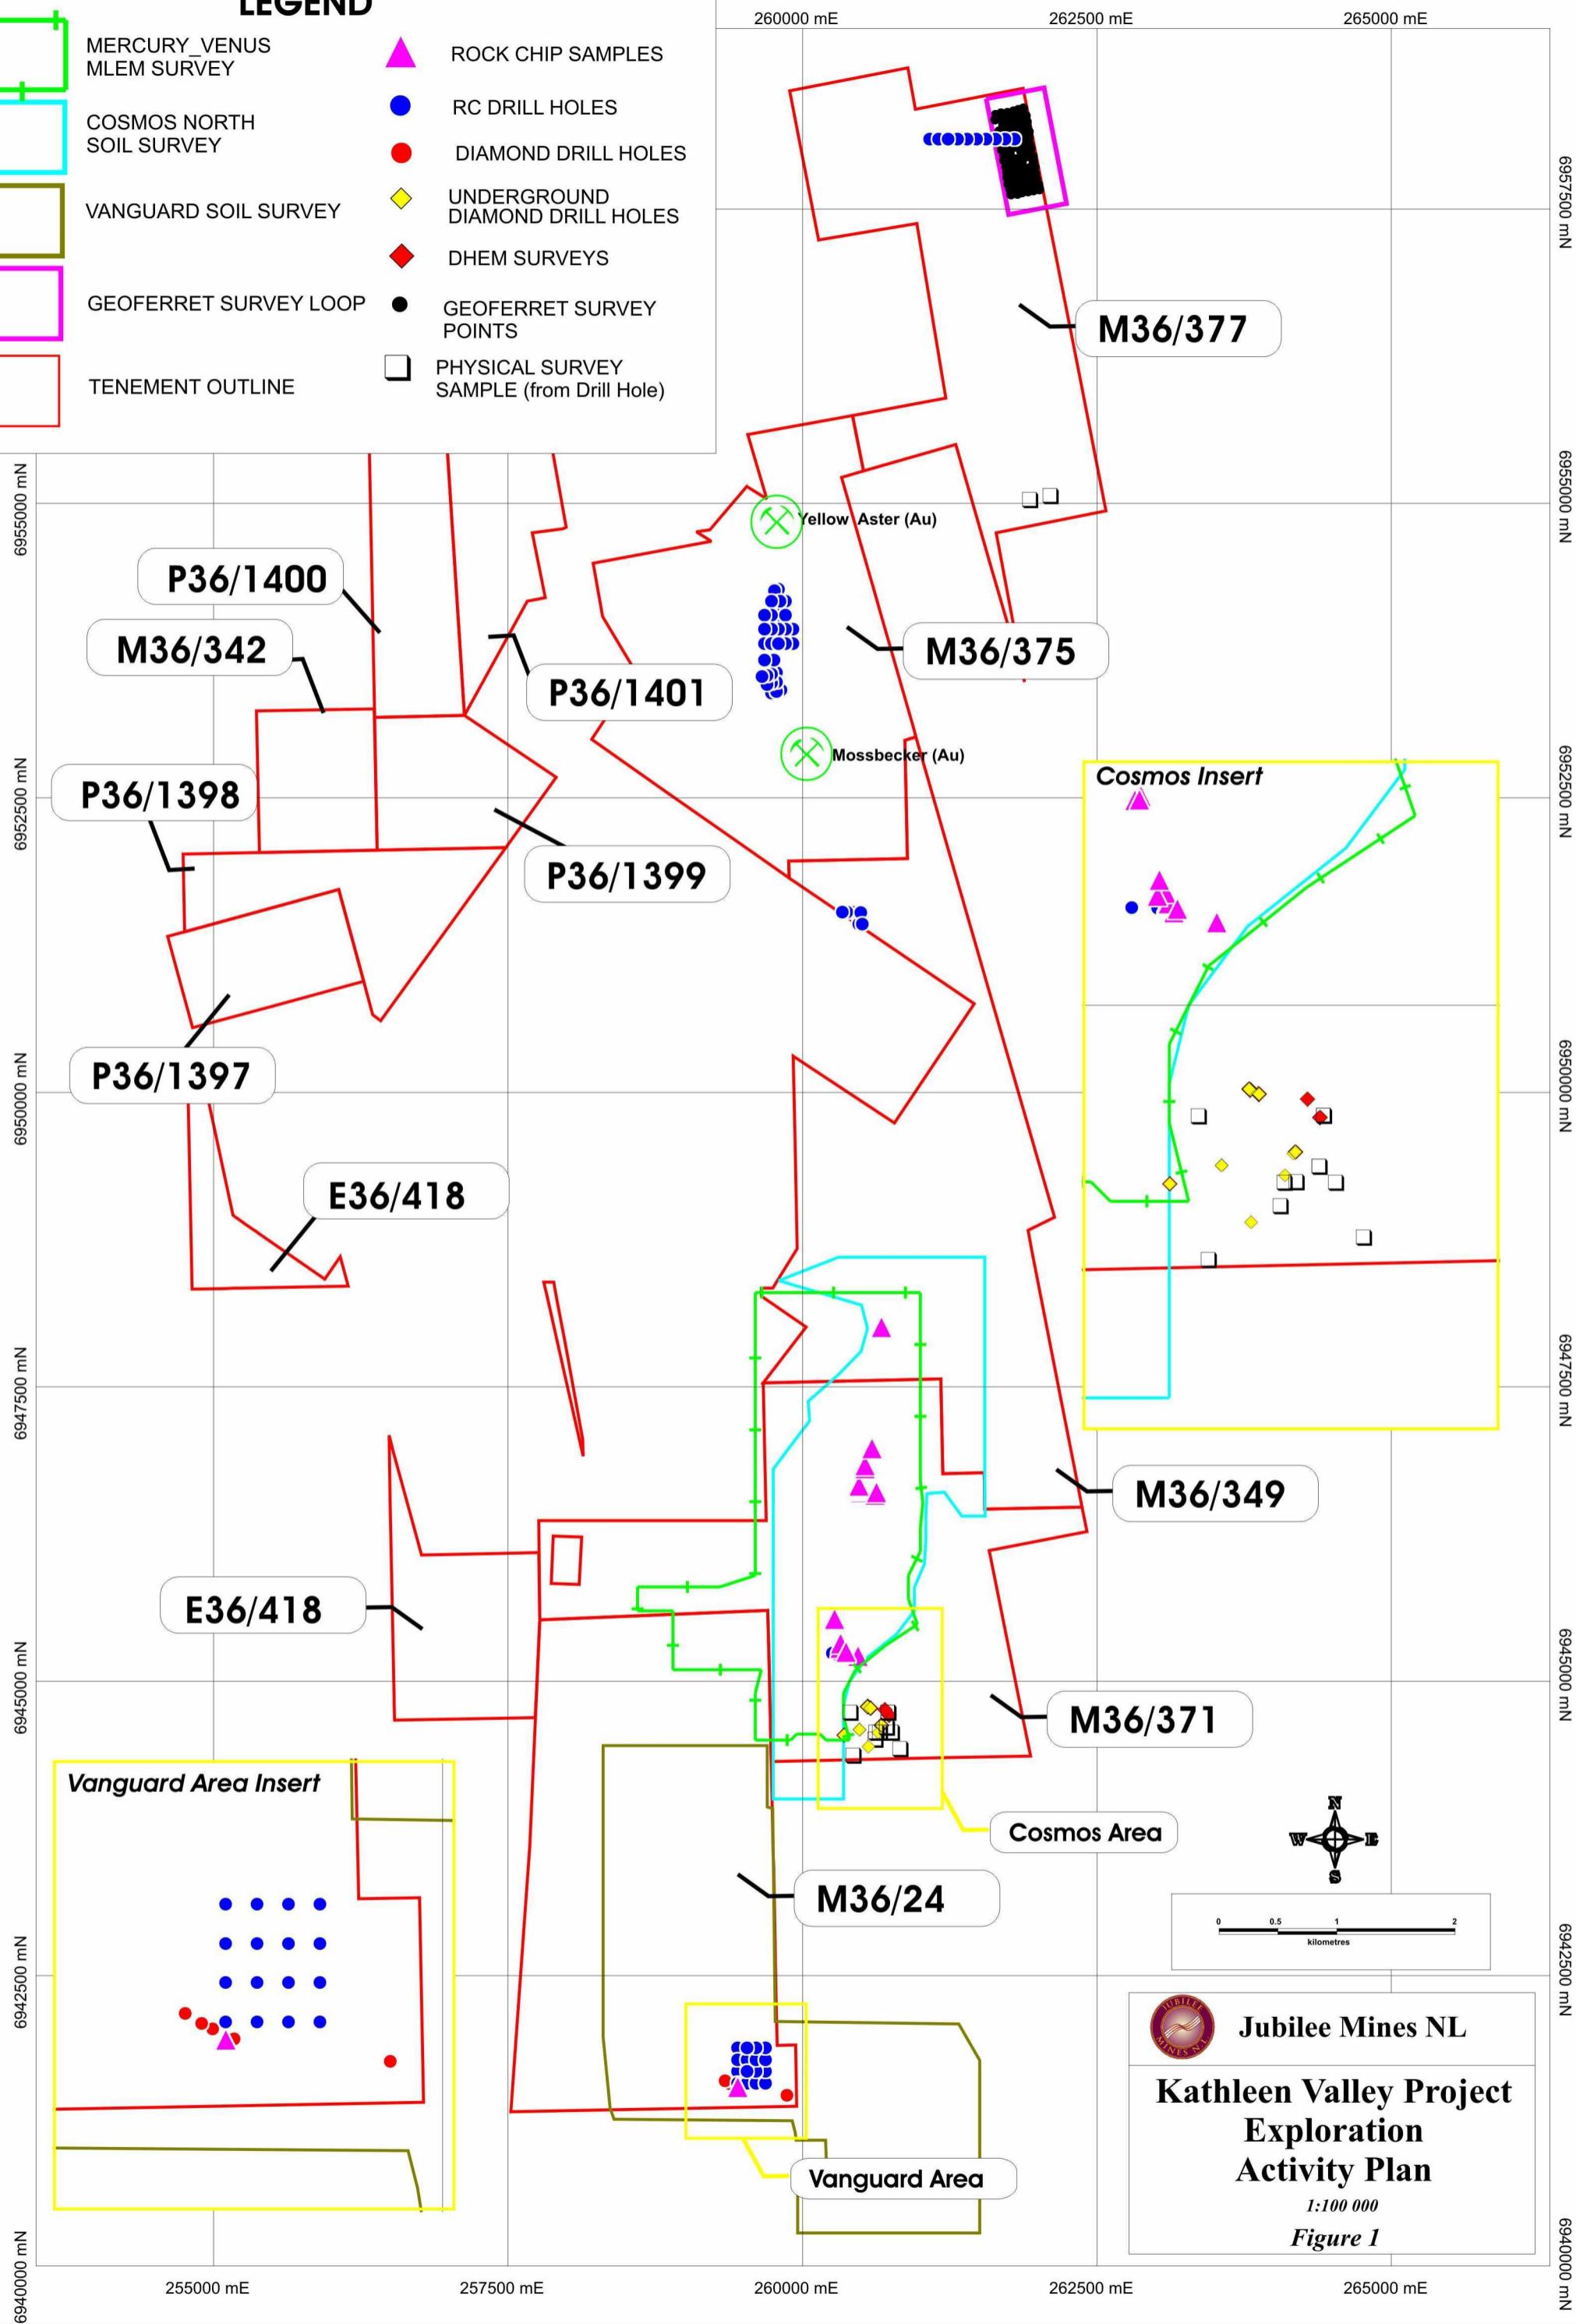

Table 1 lists the tenure that comprises the Kathleen Valley Project. All the tenements lie in the Lawlers District of the East Murchison Mineral Field. Figure 1 gives a visual representation of this tenure plus a summary of exploration activity carried out during the reporting period.

Table 1: Kathleen Valley Project Tenure

1.2 Location and Access

The Kathleen Valley Project is located 40 km northwest of Leinster, 100km south of Wiluna and 370 km north of Kalgoorlie, see Figure 2. The tenure lies on the Sir Samuel (SG 51-13) 1:250,000, and on the Sir Samuel (3042) and Mt Keith (3043) 1:100,000 GSWA map sheets. The tenure lies on the Yakabindie Station pastoral lease which is currently is owned by WMC. The property is stocked with cattle.

Access to the area is via the main Kalgoorlie-Wiluna road for some 370 km north of Kalgoorlie. This road cuts through the western edge of Jubilee's tenements. Good access is provided around the project by station tracks and fence lines. Jubilee's office is located at the Cosmos Mine centred on 260500E/6946000N.

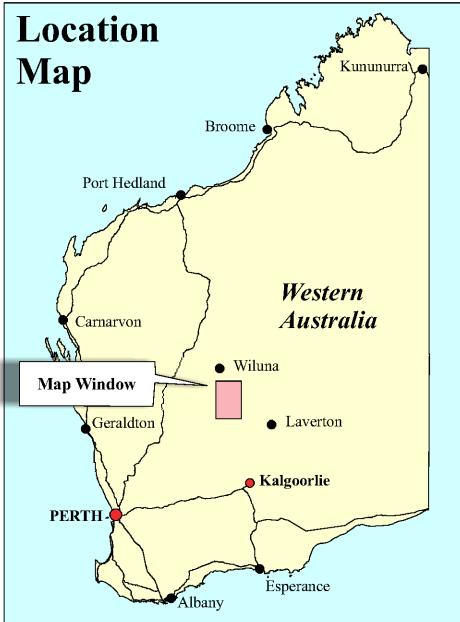

1.3 Climate and Vegetation

The climate is semi arid to arid with cool winters and hot summers. Rain is commonest in winter with periods of short-term flood and drought being common. The mean annual rainfall is 210mm. January is the hottest month with average temperatures of 22° - 36°; July is the coolest with averages of 6°- 18°.

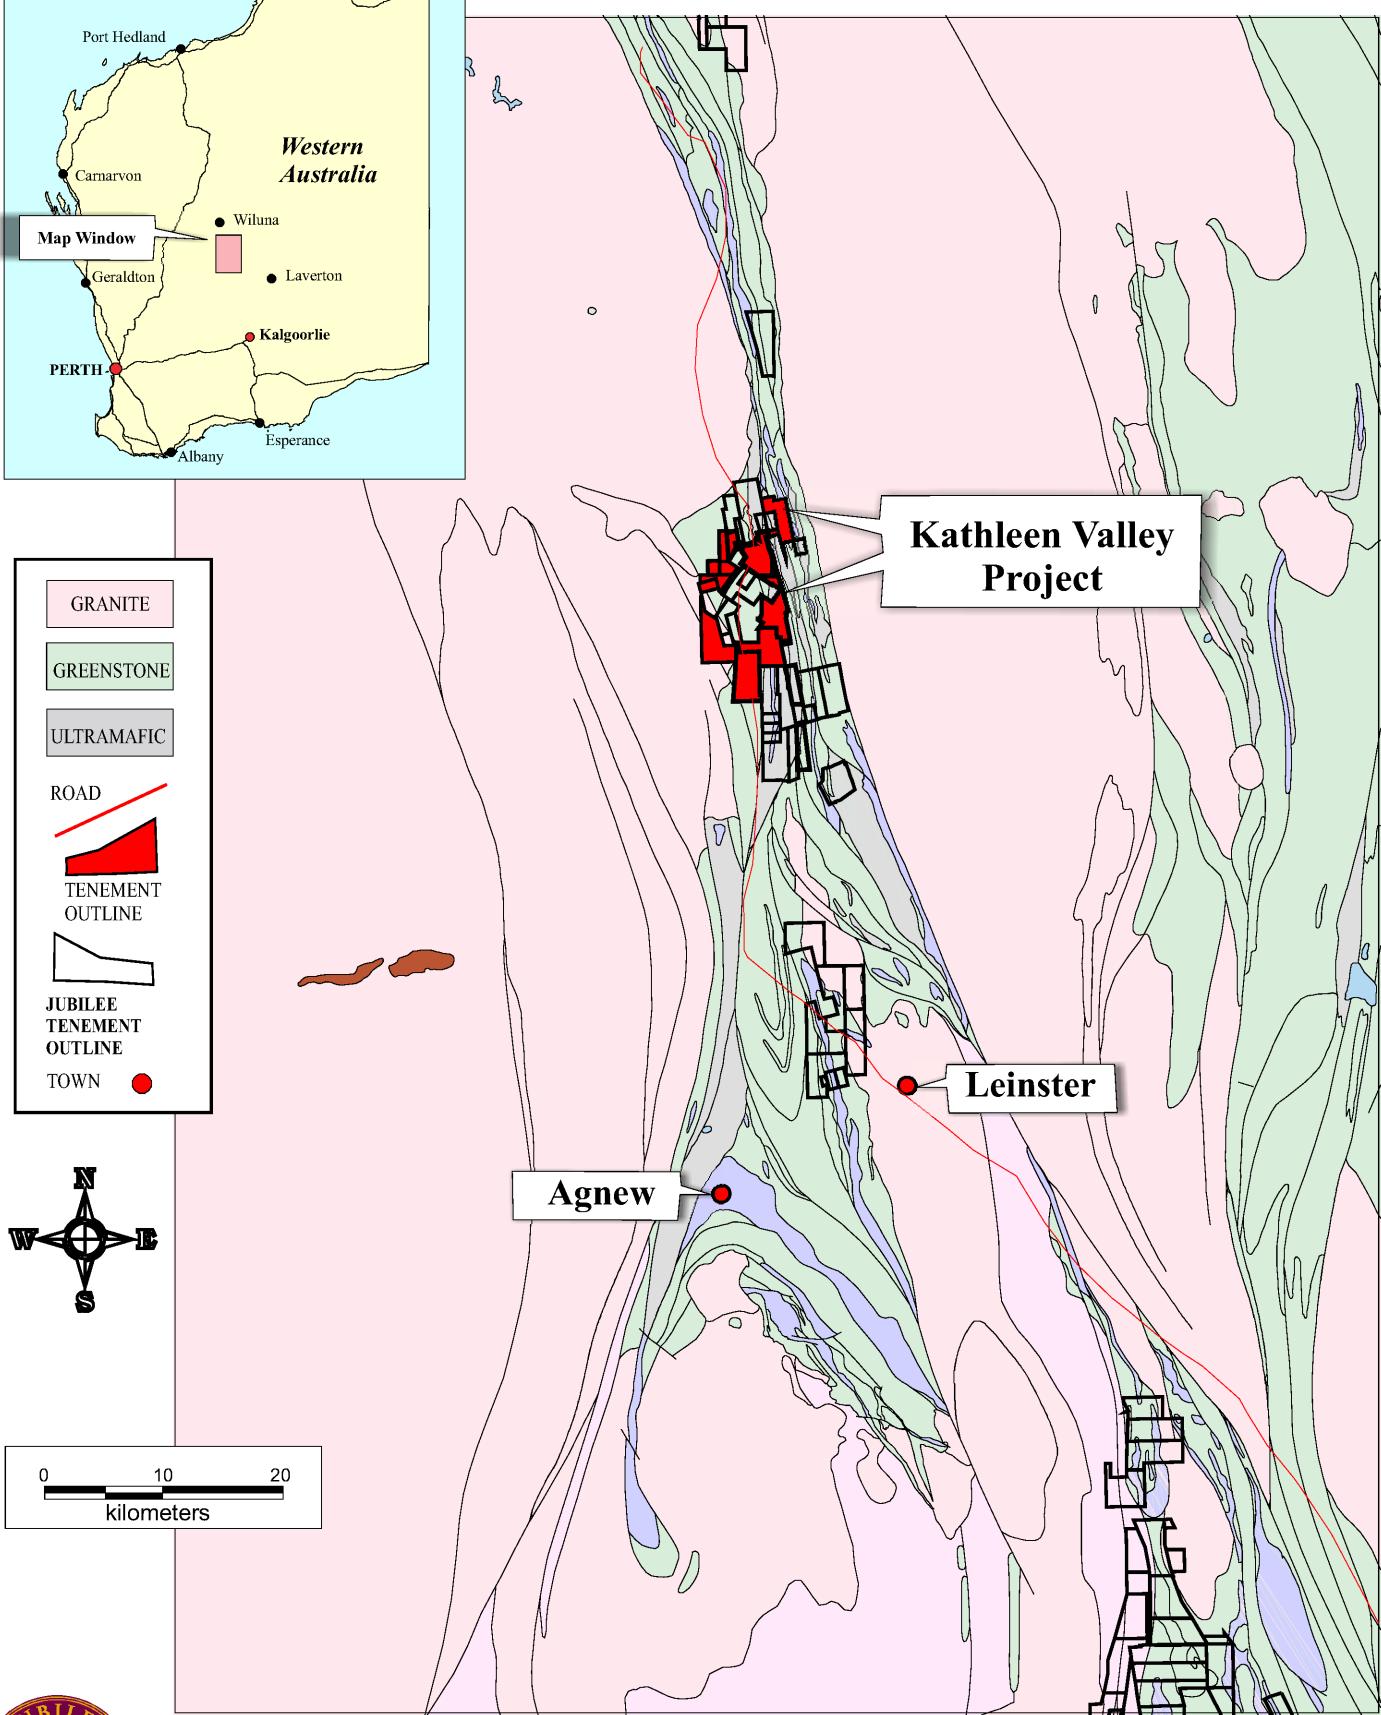

The variable physiography is reflected in the different varieties of vegetation found within the project area. Essentially the area is characterised by mulga woodlands, acacia shrub lands and both annual and perennial grasses. In areas of outcrop, mulga, sheoak, sago bush, Emu bush and kurrajong are common. Small scrub, mulga and sandalwood are common in flood plain areas. Samphire, saltbush and blue bush are found around the edges of salt lakes with spinifex and mallee confined to the sand plain country.

1.4 Physiography

The project is approximately 500m above sea level, generally undulating with topographic relief no more than 40 – 50m to the west over areas of resistant basalt and gabbro and 25 –30m to the north-east in the Five Creeks area. The topography is dominated by scree-covered hills with well developed drainage in

KATHLEEN VALLEY PROJECT Location Diagram

Jubilee Mines NL

Figure 2

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

fresh mafic rocks, which fall abruptly away to diffuse channels in granitic sand plains to the west. A well developed creek system is present across the tenure.

Thick alluvium with common lateritic lags (over mafics) dominates the western edge of the tenure. The ultramafics are deeply weathered and poorly exposed to the east of the tenure. The conglomerates and associated sediments of the Jones Creek Formation (JCC), which comprise the rest of the tenure, are generally covered with a variable thickness of gravelly scree. The lateritic profile across the project area is variably eroded and largely stripped in places.

2 Regional Geology

The tenure lies within the Agnew-Wiluna portion of the Norseman-Wiluna Greenstone belt, Figure 3. The belt is attenuated and characterized by major wrench faults, traceable over tens of kilometers, at least two phases of complex folding and generally steep dips. The prospect area lies at the junction of the northwest trending regional Keith Kilkenny Tectonic Zone and the northerly trending Miranda Shear locally referred to as the Kathleen Valley Shear. This junction is characterised by intense shearing and deformation, which has resulted in structural complexities not readily understood on a prospect scale.

The region is prospective for gold, VMS and nickel mineralisation. Gold mineralisation was exploited historically at Kathleen Valley from Yellow Aster, Nils Desperandum, and Mossbecker, and more recently at the Bellevue Gold Mine (total production ~ 800 000 oz) approximately 4.5 km south of the southern tenure boundary. Production records are incomplete; however Yellow Aster had an historical production of 51 854 t @ 20.9 g/t Au, and Nils Desperandum some 22 233 t @ 14.0 g/t Au.

Other nickel sulphide deposits within the region include Perseverance, Rocky's Reward and Harmony (69.8mt @ 2.2% combined) at Leinster, located approximately 40 km south of the tenure, and the Yakabindie (270 mt @ 0.53% Ni), Cliffs (5.7mt @ 2.3%Ni), Mt Keith (420 mt @ 0.6% Ni) and Honeymoon Well Deposits, 80km north of Cosmos with a combined resource of 155mt @ 0.7%Ni which includes the high grade Wedgetail Deposit with 2mt @ 4% Ni.

2.1 Prospect Geology

The project area can be divided into three zones - western, central and eastern. The eastern tenure block of the Kathleen Valley Project area covers the eastern zone and most of the central zone, while the western tenure block covers part of the western zone. See Figure 4.

The western zone is comprised of a northeast striking and southeast facing sequence of tholeiitic lavas, differentiated gabbroic sills and ultramafic chloritic schists. Metamorphic lithologies are amphibolitic with weak to moderate cleavage/foliation.

The eastern lithologies are made up of a sequence of mafic and ultramafic komatiites and felsic volcanic rocks and associated sediments, which dip east.

Moriarty Gabbro Sequence

Metamorphic grade is upper greenschist to lower amphibolite grade. The komatiites which are the target of nickel exploration comprise a sequence of ultramafic flows made up of olivine cumulates, variably serpentinised and foliated. The komatiites are commonly intruded by felsic porphyries. In contact they become serpentinised and sheared talc carbonates. The eastern lithologies generally face east except in the northeast of the tenure at Five Creeks where the komatiites generally dip and face west.

The western and eastern zones are separated by the predominately heterogeneous conglomeratic Jones Creek Conglomerate (JCC), which occupies a large north-south graben structure. This unit with its associated felsic volcanics and sediments lies unconformably over the western gabbroic units. The sequence is composed of well rounded granitoid pebbles and boulders (up to 1m long) set in an arkosic matrix. To the east and south the unit includes increasing amounts of mafic and calc-silicate fragments (Carriport area) with the matrix becoming increasingly volcaniclastic. Where observable the upper and lower contacts are zones of high strain indicating their tectonic origin.

Pegmatites, which were regionally explored during the reporting period, are common within the western and central lithologies. They strike northwest to southeast, are massive, zoned and sub vertical in character and are generally in the order of 20cm to 12m in width. They are composed of quartz, feldspar, muscovite, tourmaline, tantalum and a purple lithium mineral spodumene and/or lepidolite.

Gold mineralisation at Yellow Aster is believed to be confined to a set of quartz veins which dip at 30° north to the north of 10600N (local grid) and 30° south to the south of 10600N within felsic conglomerates stratigraphically equivalent to JCC. It is interpreted that these two vein sets are offset by faulting. The mineralisation is confined to high grade shoots at the margins of the quartz veins. At Nils Desperandum gold mineralisation is confined to two shallow dipping (30° NNW) quartz veins. Gold mineralisation at Mossbecker-Carriport is localised within sericite-arsenopyrite quartz veins along a flat southwest dipping thrust that obliquely cuts the felsic conglomerate. Gold mineralisation at the Main Road Pit (mined by Hunter) is localised along a sulphidic chert which occurs along the faulted contact between the ultramafic talc carbonate schist and the hanging wall amphibolites. At the Bellevue Gold Mine, 4.5 km south of the southern tenure boundary, gold mineralisation is localised within the Mt Goode Basalts intruded by felsic porphyries within the Bellevue Shear. Gold occurs along the shear plane within dilational jogs.

The western contact of the central zone is both sheared and unconformable (Ronk 1995). The eastern contact is poorly exposed and deeply weathered with areas of transported cover completely obscuring the contact. Observations by Ronk and Fey (1998) suggest that this contact is faulted. Archibald (1995) called this zone the ‘Kathleen Valley Shear Zone’, which he described as a broad zone of anastomosing shears.

Three structural events are recognised within the project area, D₁ – D₃. The D₁ event was a WNW-ESE compression resulting in ductile deformation, N-S striking thrusts, and rare steeply south plunging folds contemporaneous with granitoid emplacement. Oblique sinistral reverse movement occurred on pre existing structures e.g. Yakabindie Shear and the Hotel Fault.

The D₂ event was a WNW-ESE compression, which progressively rotated to a NE-SW compression resulting in ductile deformation, regional N plunging folds, and early sinistral and later dextral strike-slip movement on shears. Regional dextral wrenching on the Miranda Shear produced complex vein arrays.

The D₃ event is believed to be associated with the emplacement of gold mineralisation. The event is associated with NE-SW extension, brittle-ductile reactivation of shears with normal sinistral movement on NW-NNW shears. Both Main Road and Mossbecker mineralisation is believed to be controlled by this event on NNW structures.

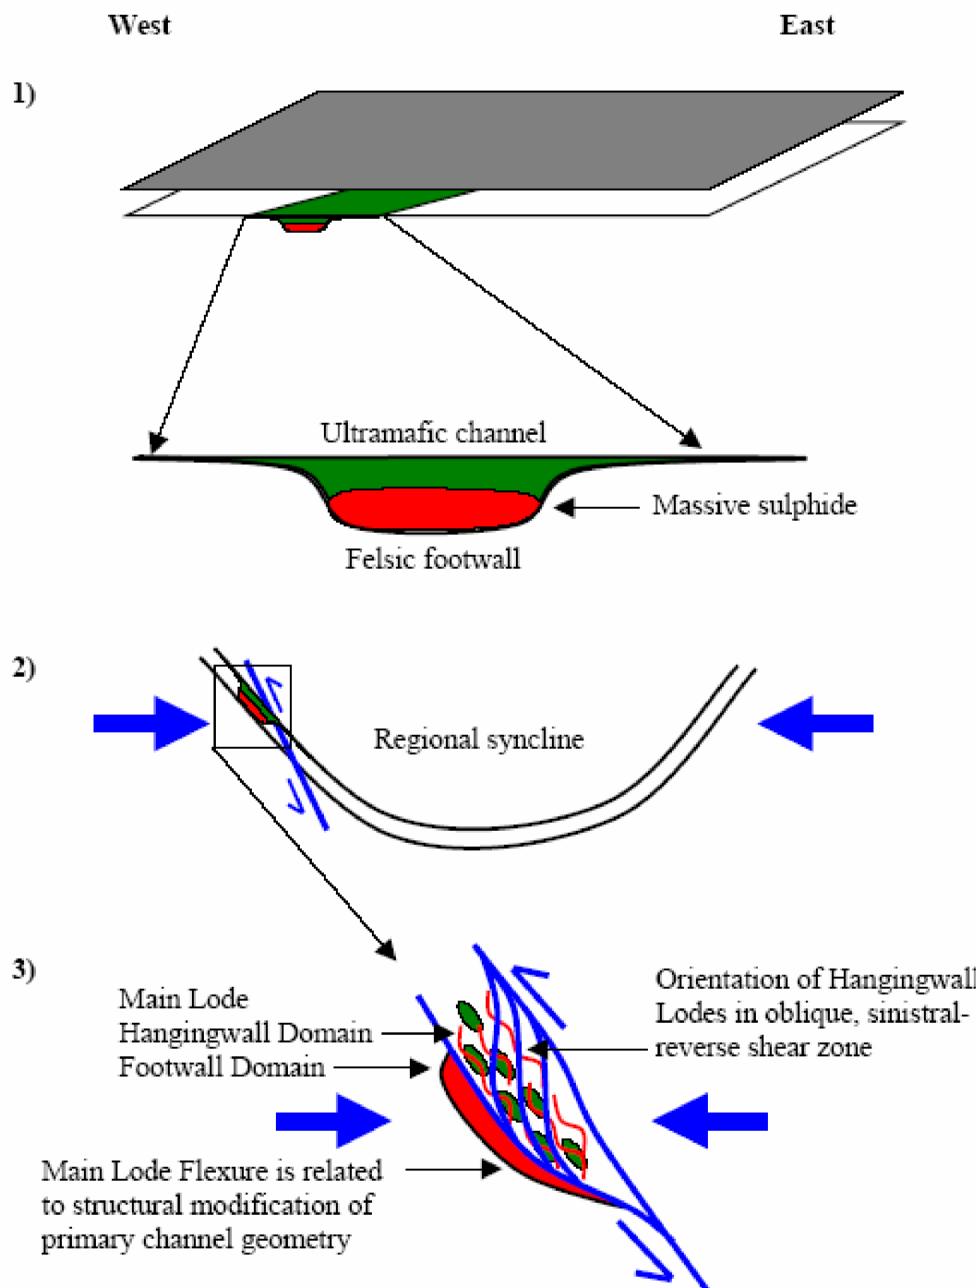

2.2 *Geology of the Cosmos Deeps Nickel Sulphide Deposit*

The Cosmos Nickel deposits are komatiite-associated massive nickel sulphide deposits located on the basal ortho-cumulate/felsic volcanic/volcaniclastic contact. The Cosmos Nickel deposit was mined out in 2003 when mining commenced on the Cosmos Deeps massive nickel sulphide ore body.

The Cosmos Deeps mineralisation lies some 470m below surface. The ore is located in 2 main zones, the **Main Lode** and **Hangingwall Lode**. The **Main Lode** is interpreted to represent primary massive sulphide comprised predominantly of matrix-massive sulphides. The sulphide assemblage comprises pentlandite set in a fine grained groundmass of pyrrhotite and pentlandite with lesser pyrite and chalcopyrite. Average nickel grades are typically between 12-13% depending on the amount of wall rock within the matrix. The sulphides occupy an interpreted basal embayment within felsic volcanic footwall to the Cosmos Ultramafic. The host ultramafic at this location appears to have been faulted out leaving the Cosmos Deeps ore body entirely hosted within felsic volcanics. The ore strikes 340° NW with a shallow easterly plunge. A flexure occurs within the Main Lode at the 9945 level. The average dip above this level is at 70° and the average dip below is at 50°. Closed joints are more common in the upper steeper dipping zone compared to quartz-carbonate veins below the 9945 level. This flexure is believed to be related to the primary shape of the main lava channel. This flexure has defined the mining methods employed underground with ore above the flexure being mined via open stoping whilst that below by cut-and-fill methods.

The **Hangingwall Lode** lies some 20-30m above the Main Lode and is roughly sub- parallel to it. Sulphides are commonly sheared and brecciated as blebby and stringer sulphides variable in grade from 1-15% Ni and comprised of both pentlandite and pyrrhotite as above. The Hangingwall Lode lies within a large shear zone which has developed along the upper margin of the ultramafic channel that hosts the massive nickel sulphides (M\$). The Hangingwall domain lies within

an oblique sinistral-reverse shear zone which has developed along the upper contact to the primary ultramafic channel. The average strike of the Hangingwall Lode is N-S which is probably related to the S-C shear fabric development during E-W compression. The shearing has occurred along the upper margins of the ultramafic channel where the hydrothermal alteration is greatest. A schematic cross section showing the stratigraphic and structural features of the Cosmos Deposit is given below.

3 Discussion of 2005 Work

3.1 Soil Geochemistry-Mercury-M36/349, 371

A soil survey was undertaken over an area north of Cosmos previously identified as the Mercury Prospect to geochemical map and evaluates the known fertile komatiite units and to provide a fundamental exploration data set for this mineralized region. A -250 um soil survey on a 200 x 50 m grid was undertaken to provide a fundamental exploration data set for this mineralized region. A total of 620 samples including duplicates and certified reference materials (CRM's) were submitted for analysis. Sampling was conducted using the prescribed Jubilee Mines Soil Sampling protocol (Appendix 1) with (CRM's) and field duplicates included at a rate of 4 per 100 samples (i.e. QAQC represents 8% of total samples).

Sampling was undertaken by **Jeandrex Field Services**. Basic field information was collected during sampling in accordance with the Jubilee Soil legend, see Appendix 1.

Soil samples were dispatched to the ACME Laboratory in Vancouver, Canada for analysis by aqua regia using the Assay Scheme **Gp1FMS** for 39 elements. This method utilises a 30 gram charge which has been leached with a 3 acid (HCL-HNO₃-H₂O) digest. Analysis is by ICP/ES and MS.

Data Manipulation and Evaluation

Elements were transformed to evaluate the significance of their correlations and to enable outliers to be identified and perform multivariate statistics (MVS).

A number of techniques were then used to maximize the information gained from the data set to identify anomalous areas including:

- Element correlations
- Identifying outliers through Z scores (data transformed)
- Identifying outliers through key breaks in data (normal probability plot)
- Element ratios (Ni:Cr, Cu:Zn, Kambalda Ratio)
- Principal Component Analysis (PCA)

Anomalies Generated.

Following the geochemical evaluation of the raw and transformed data sets 10 geochemical anomalies have been generated. Of these, five are related to Ni associated with komatiitic lithologies, three are Au related and the remaining two are low order related PCA6 structural trends to structure, see Figure 5.

COS_003 – Cosmos West – Cosmos North: Characterized by anomalous Ni, Cr KR, NiCr, Pt +/- Cu and overlying the Comos ultramafic unit. Field inspection indicates the Cosmos North and West Anomaly is situated on an erosional landscape (truncated) described as a stripped pediment covered by deflated resistant materials. These materials are dominated by quartz rubble with occasional disconnected ferruginous duricrust on very slight topographic mounds.

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

Soils are typically thin (<0.5m); these and underlying weathered lithologies are hardpanised. Isolated mounds of non-ferruginised weathered komatiites are present containing massive apple green siliceous serpentine in contact with ferruginised serpentine (gossanous) material (6945255mN 260348mE). Saprolitic dunitic komatiites (6945316mN, 260324mE) are occasionally preserved in stream channels. The anomaly is truncated to the north by a creek system. Twelve rock-chip samples were collected for analysis with three rock chips in the north of the anomaly returning an average of 1470 ppm Ni and 165 ppm Cu (see 1.2).

Recommendations: It is strongly recommended to infill this anomaly using a 30 x 30m offset grid.

Priority: High

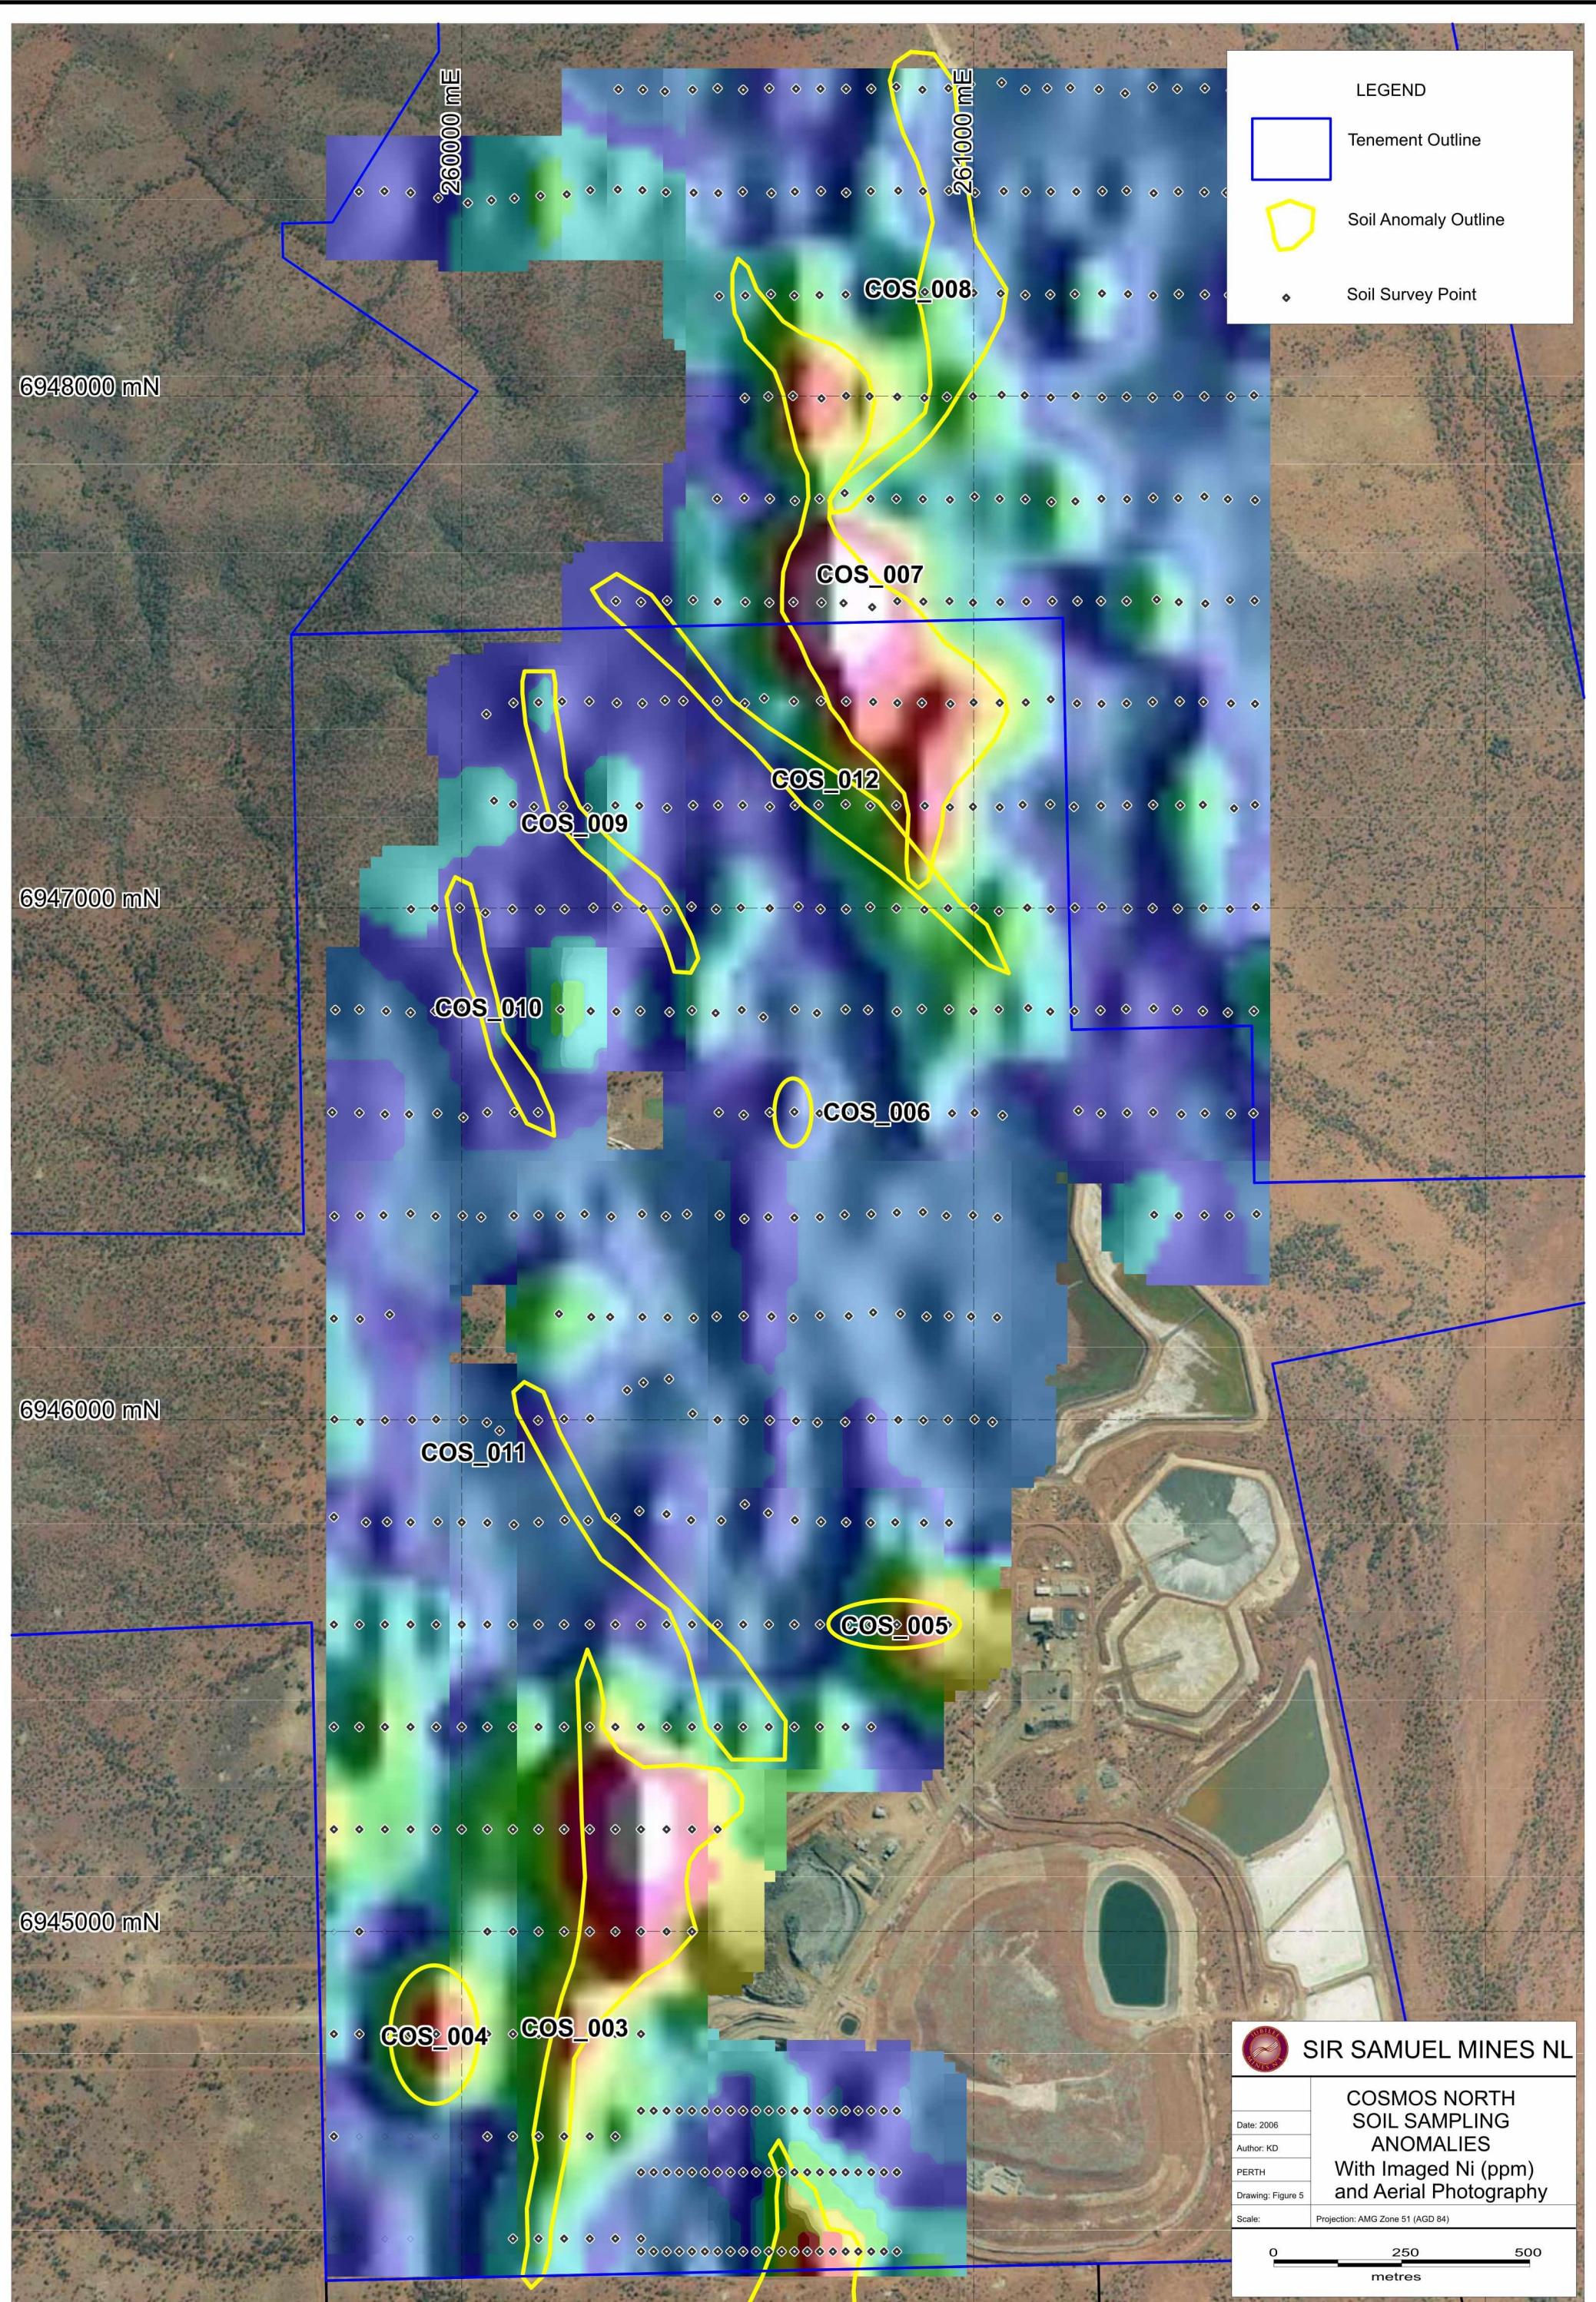

Figure 5

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

COS_004 – Far West Cosmos: Characterized by anomalous Ni, Cr KR, NiCr, and Pt +/- Cu and overlying a possible extension to the Comos ultramafic unit, although only developed on one line. Field inspection indicates Far West Cosmos Anomaly is situated on an erosional landscape (truncated) described as a stripped pediment covered by deflated resistant materials. These materials are dominated by quartz rubble with occasional disconnected ferruginous duricrust on very slight topographic mounds. Soils is typically thin (<0.5m).

Action and Recommendations: Field inspect to ensure this anomaly is a function of contamination

Priority: Low

COS_006 – Venus: A single point anomaly characterized by anomalous Ni, Cr KR, NiCr, Pt +/- Cu an extension to the Comos ultramafic unit. The Venus area is situated on an erosional landscape (truncated) described as a stripped pediment covered by deflated resistant materials. These materials are dominated by quartz rubble and ferruginous duricrust. Soils is typically thin (<0.5m) with occasional “day-lighting” of underlying silicified and ferruginous lithologies. The anomaly is truncated to the north by a creek system. Eleven rock chip samples have been collected for analysis. The best rock chip on the anomaly returned 142 ppm Cu, 810 ppm Ni, 4 ppb Pd & 11.4 ppb Pt with a second rock chip taken 380m north returning 442 ppm Cu, 435 ppm Ni, 3 ppm Pd & 8.7 ppb Pt (see **1.2**).

Table 5: Cosmos 6-Soil Anomaly –Key Element Data

AMG North	AMG East	Sample ID	Au ppb	Ag ppm	As ppm	Cr ppm	Cu ppm	Fe %	Ni ppm	Pd ppm	Pt ppm	Zn ppm
6946602	260650	4000326	0.4	0.006	3.4	368.4	26.99	4.26	30	-0.01	0.005	12.2

Action and Recommendations: Following field inspection and confirmation of a residual regolith environment it is strongly recommended to infill this anomaly using a 30 x 30m offset grid as part of the Cosmos North infill program.

Priority: Medium - High

COS_007 – Mercury: Characterized by anomalous Ni, Cr KR, NiCr, and Pt +/- Cu and overlying the Comos ultramafic unit. The Apollo region is typically a stripped erosional landscape with low topographic relief. Lithologies are well exposed, weathered with occasional ferruginous Fe-stone developed at surface. Soils is typically thin (<0.5m). One rock chip sample has been collected for analysis at 6948000mN 260670mE (see 1.2) returning 244 ppm Cu, 1435 ppm Ni, 14 ppb Pd and 16 ppb Pt and indicating the presence of a **NiS gossan**.

Priority: Low.

3.2 Soil Geochemistry-Vanguard-M36/24

A total of 446 soil samples (including duplicates) were collected and assayed as per the Mercury soil sampling, on a 200 x 50m grid.

The landscape of the Orleans-Vanguard Area is generally flat-lying, with large areas of alluvial floodplain, colluvium, and the Lake Miranda lacustrine environment to the south. Ridges and low hills of greenstones are common to the west around Bellevue.

The regolith within the Vanguard region is situated with in a truncated erosional landscape. A -250µm soil survey was undertaken over M36/24 (Vanguard-Kathleen Valley) to:

- Provide a fundamental data set for the region.
- Map out the lithologies within these tenements and provide a comprehensive data set to aid in geological mapping.

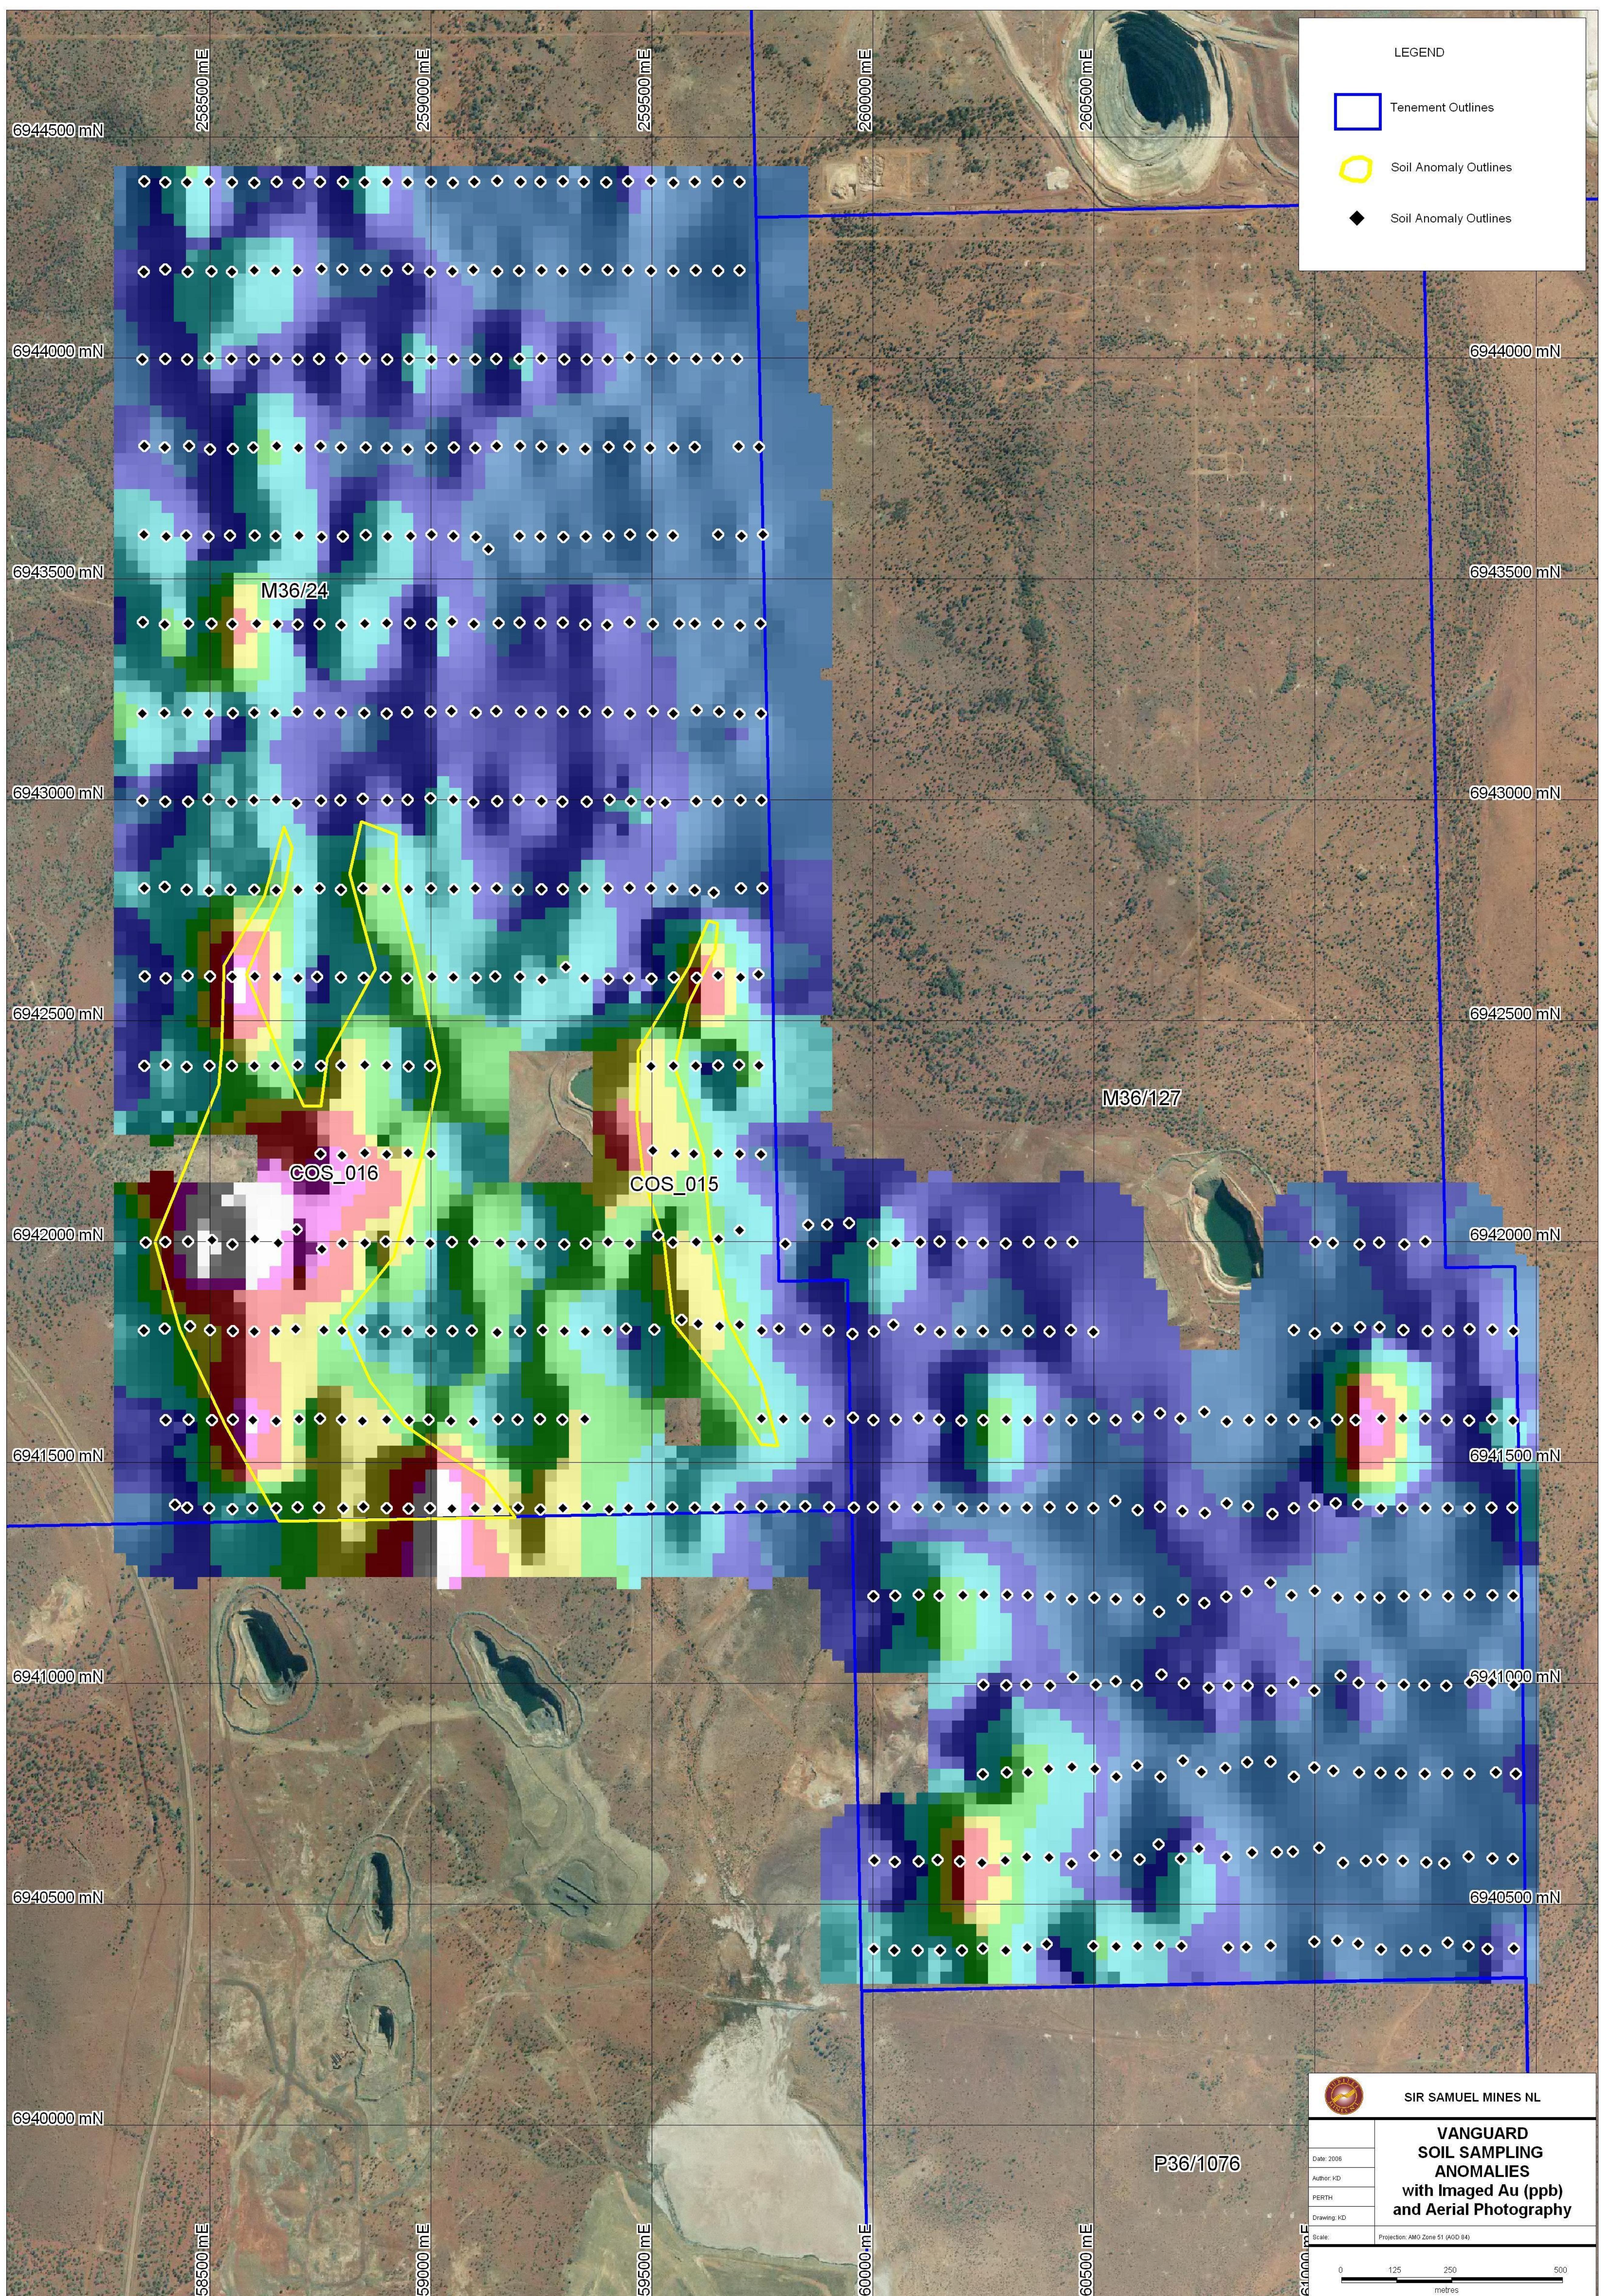

Figure 6

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

- Define potential areas which may be host to NiS within the area sampled and define areas of interest for potential Au mineralization.
- Map out mineralization/lithological trend through shallow cover and provide a comprehensive data set for regolith mapping.
- Identify potential controlling structures related to and controlling Au and Ni.

No nickel anomalies were identified within the dataset, two gold related anomalies COS_15 and COS_16 have been historically intensively drilled, see Figure 6.

3.3 Rock Chip Sampling

During soils sampling reconnaissance and field checking of anomalous sites a total of 32 rock chips were collected from Apollo, Venus, Vanguard and Cosmos North. Samples were dispatched to ALS Laboratory for analysis of Al, Ca, Cr, Cu, Fe, K, Mg, Mn, Na, Ni, Pb, S, Ti, V, Zn, Ag, As, Bi, Cd, Co, Mo, Sb, Se, TE, W, Zr, Au, Pt and Pd. Au, Pt and Pd were analysed by method PGM-MS23, elements Ag to Zr were analysed by method ME-MS62 and the remaining elements by method ME-ICP61s.

Method PGM-MS23- This is a precious metal analysis utilising a 30 gram charge, aqua regia digest with Fire Assay-ICPAES (Inductively coupled plasma atomic emission spectrometry) detection.

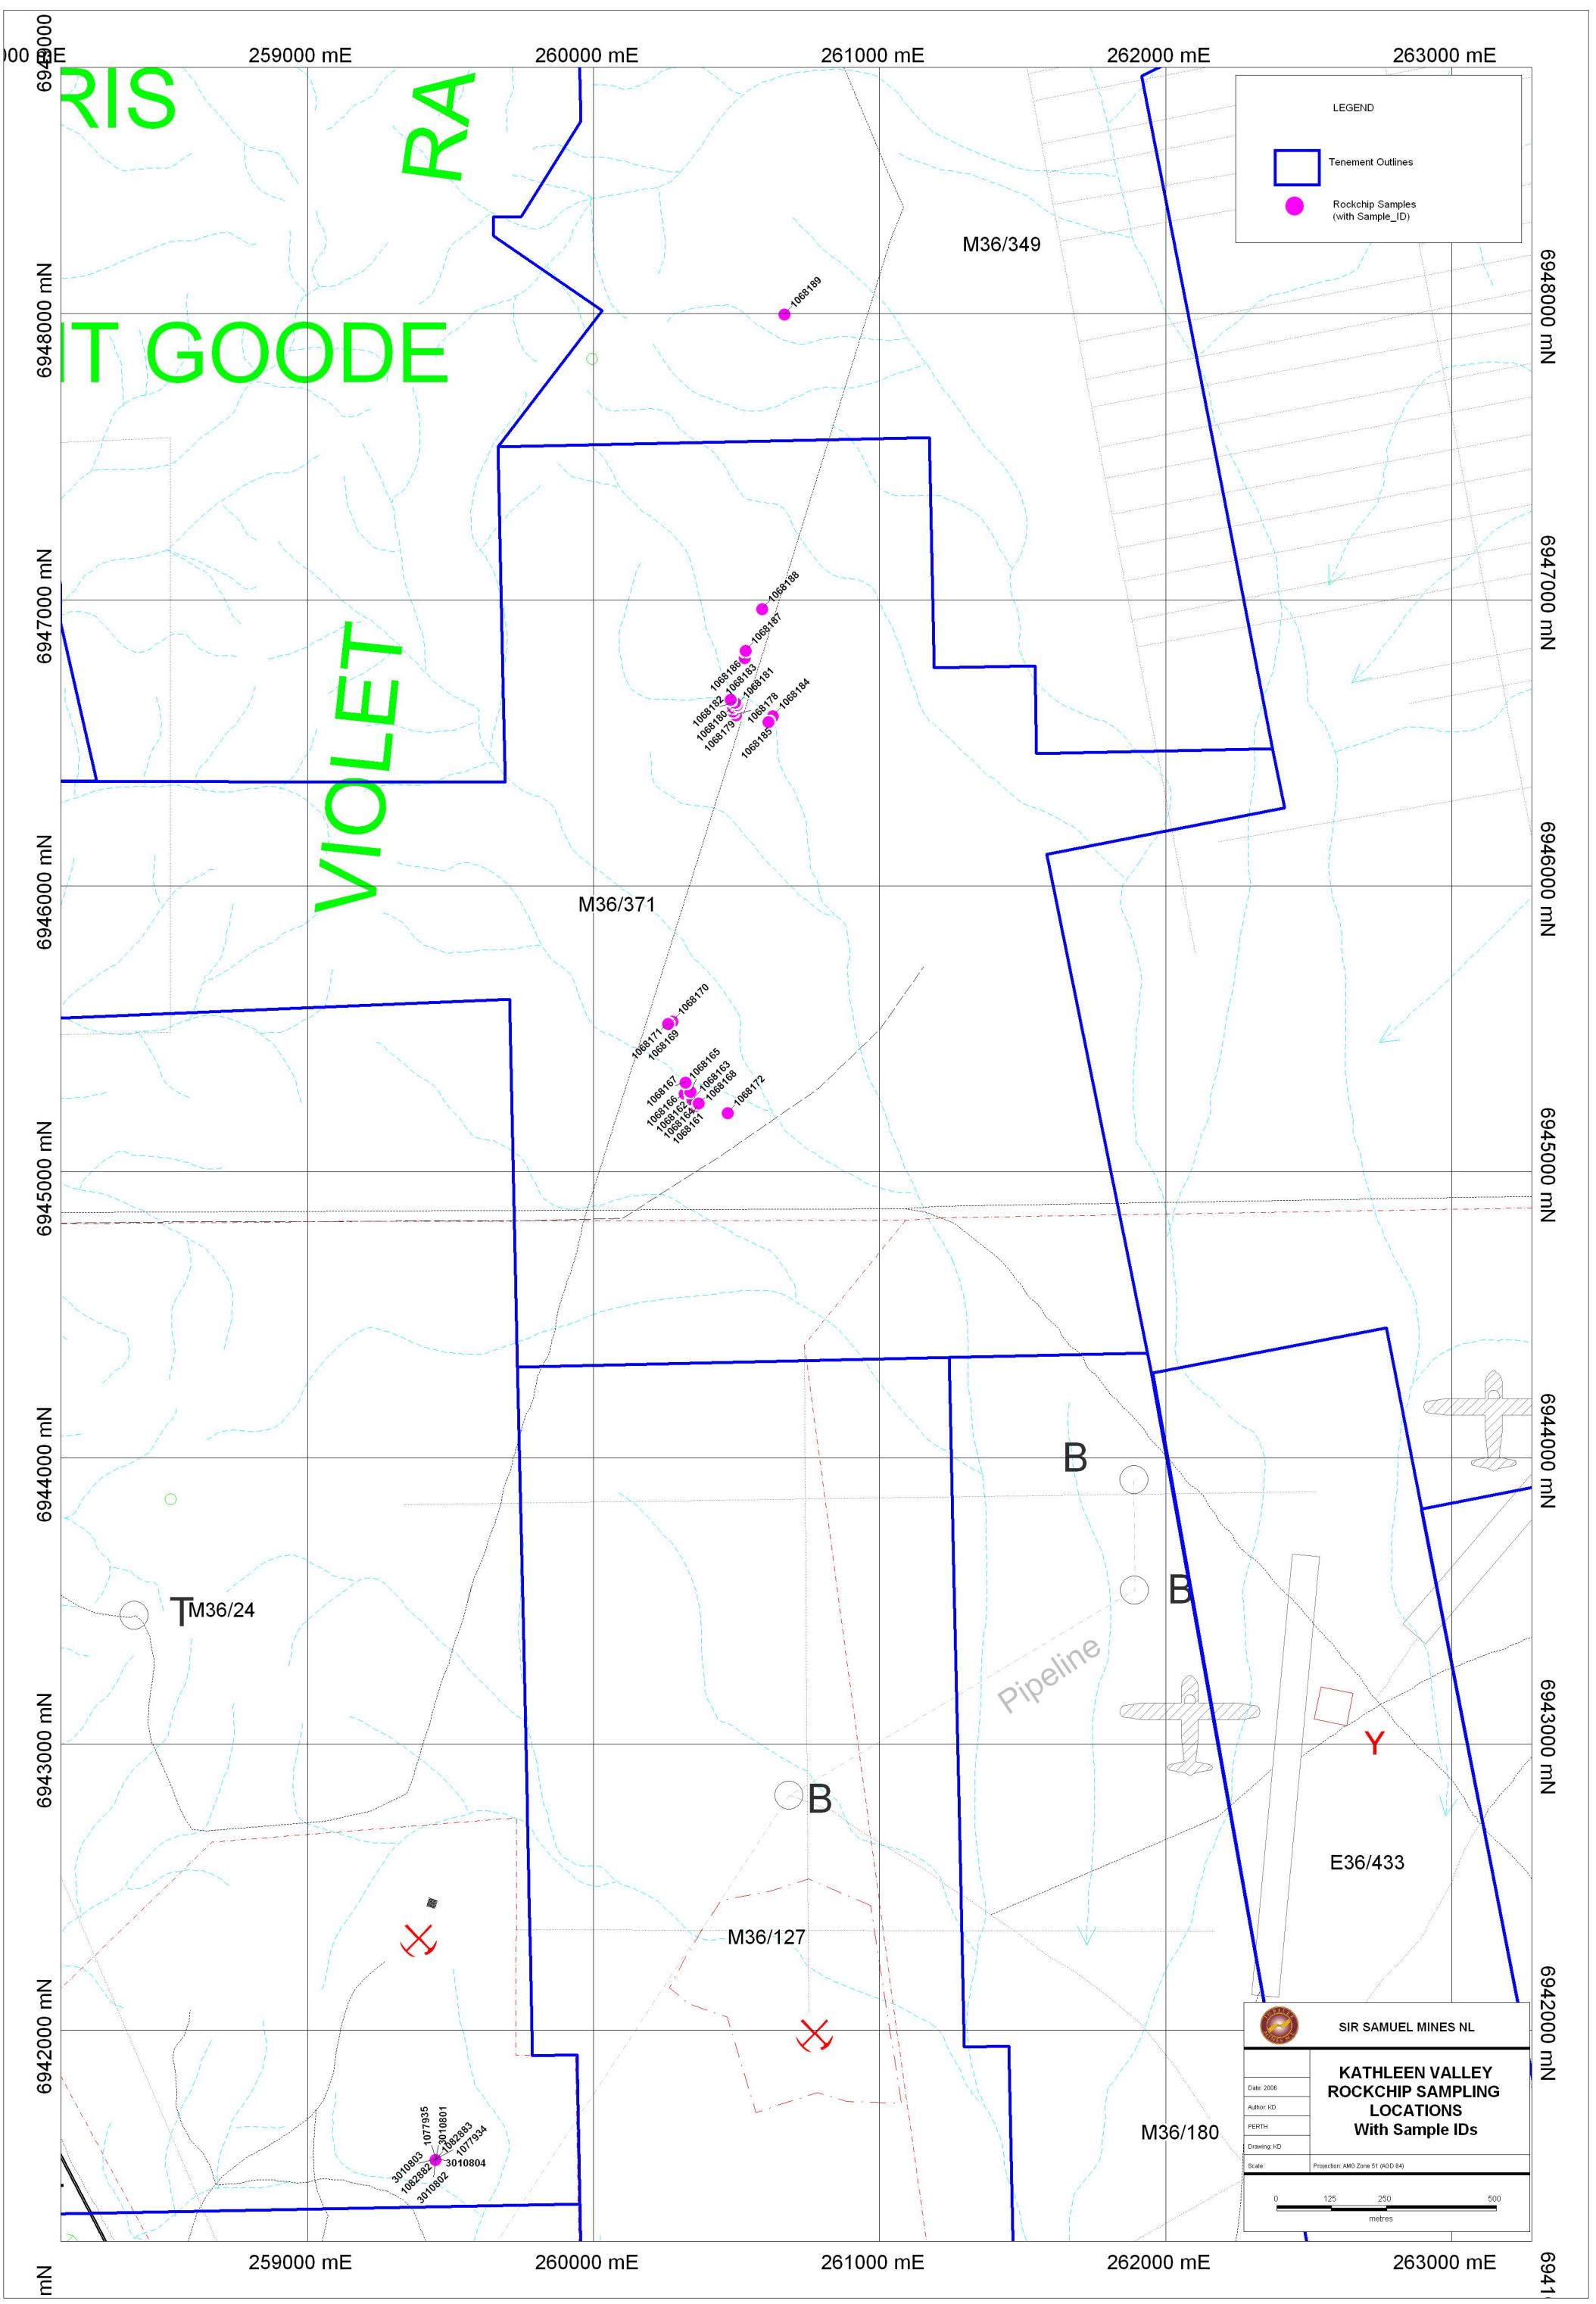

Method ME-MS62s- This method uses a 4 acid digest of HF-HNO₃-HClO₄ acids with an HCL leach and ICP Mass Spectrometry detection.

Method ME-ICP61s- This method uses a 4 acid digest of HF-HNO₃-HClO₄ acids with an HCL leach and inductively coupled plasma atomic emission spectrometry (ICP) detection.

Sample details are given in Table 9 with raw assay results given in Appendix 2. Samples are located in Figure 7. Sample results are discussed above in 3.1 in conjunction with soil analysis.

Table 9: Rock Chip Locations

3.4 Review of Pegmatites & Copper Potential of Kathleen Valley

During the period a desktop review of the potential of the tenure to host economic tantalum niobium (Ta_2O_5/Nb_2O_5) within the pegmatite dyke swarms and copper mineralisation within the gabbroic layered intrusion was researched. Data was sourced mainly from previous DoIR annual technical reports.

Pegmatites

Extensive rock chip sampling was conducted over the pegmatites between 1998-2002 (all reported previously to the DoIR). No niobium or Li enrichment was encountered. The best grades identified are defined in Table 10.

Table 10: Maximum Kathleen Valley Pegmatite Results-1998

Sample ID	AMG East	AMG North	Li %	Ta ppm	Nb ppm	Sn %
KVTGR055	260267	6954160	0.381	323	63	0.00987
KVTGR049	259888	6948444	0.0019	407	46.6	0.00176
Greenbushes			2.8	590	400	0.15

The Greenbushes Pegmatite deposit within Western Australia is a benchmark; it produces a **2.8% Li and 590ppm Ta concentrate**. Within the Kathleen Valley pegmatites the Ta is enriched on the edges of the dyke with Li being enriched within the centre of the dykes. The Kathleen Valley Pegmatites are generally between a width of 0.2-12m and <200m to ~1km in length. Swarms are concentrated around Mercury Prospect and Mossbecker. The grade and dimension of the dykes sampled indicate that they are unlikely to host significant economic accumulations of Li and Ta.

Copper

Soil sampling and rock chip sampling in 1996-2000 highlighted Au/Cu anomalies coincident with NW trending shears within the Kathleen Valley Gabbro Complex. This mineralisation is probably related to Kathleen Valley – Bellevue gold mineralisation. The NW-NNW shear zones, and the Hotel and Mt Mann Faults are interpreted to be deep fault zones, along which hydrothermal fluids have migrated and been deposited within zones of rheological contrast. Gold and possibly silver are related to this event, and the copper is interpreted as being leached from the gabbro. Copper is commonly enriched in the pyroxene lattice of gabbros, and metamorphism of the pyroxene to hornblende would cause remobilisation and precipitation of the metal, producing the observed copper. No significant Cu/Au values were returned from the gabbroic shears however NW trending shears felsic porphyry and sediments produced a number of anomalous Cu/Au rock chips, see Table 11.

Table 11: Anomalous Mercury Cu/Au Rock Chips

Prospect	Tenure	Geology	Sample ID	AMG East	AMG North	Cu %	Au ppm

3.5 Resource Modelling- Mossbecker-Yellow Aster-Nils Desperandum

A resource estimate was conducted on the Mossbecker/Yellow Aster gold in Jones Creek Conglomerates. **These resources are not JORC compliant.** They are summarised below in Table 12.

Table 12: Summary of Kathleen Valley Gold Resources

Resource	No of	Block	Model	Kriging	Drill	Cut-off	Model	Grade	Au
	Domains	Size(m)	Orientation	Method	Density	g/t Au	Tonnes		Oz
Mossbecker	6	10x5x2.5	0°	Ordinary	25 x 12.5m	0.00	1,050,887.00	2.29	77,270.00
Yellow Aster	6	10x5x2.5	0°	Ordinary	25 x 12.5m	0.00	2,298,096.00	1.44	106,385.00

Variography Package Snowden V6.00

Mining Package GEMS V5.52

3.6 RC Drilling

RC drilling was carried out at a number of prospects and targets during the period, details of each program are given below. A total of 66 holes for 6655m and 5269 laboratory assay samples were completed. All of the holes were drilled by contractor **Target Drilling** using a **Hydco 350 5.25"** drill rig fitted with a 1050 CFM 380 PSI air compressor with a 4^{1/2} " drill string and 5^{1/2} " face hammer, with the exception of the Five Creeks drill holes, FCC29-38, which were drilled by contractor **Drillcorp Western Deeps Hole** using a **Schramm 5.5"** face hammer.

The Ilias, South Yellow Aster and North Carriport drilling targeted the gold mineralisation within the Jones Creek conglomerates. Due to the complexity of gold sampling and the nugget effect caused by coarse gold, the following sampling procedures were adopted:

- Drill samples were collected every meter and cone split into calico bags.
- The bulk sample was tipped on to the ground in sample rows of 20.
- Spillage outside of the splitter was kept to a minimum.
- Splitter was cleaned by air hose regularly.
- No wet samples were put through splitter. Wet samples were collected in polyweave bags and left to drain. These were spear sampled once the excess water has drained.
- No over drilling in the last metre was allowed to prevent irregular sample sizes.
- Holes were blown dry at the start of a new rod before drilling commenced, in order that the samples were kept dry.

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

- With the use of water injection dust was minimised to reduce the loss of fines.
- Weights of calico bags were recorded.
- A duplicate sample was collected on the basis of 1 in 20 with standards inserted on the basis of 1 in 25.

Samples were dispatched to ALS Chemex Laboratory in Perth for analysis of Ag, Al, As, Co, Cr, Cu, Fe, Mg, Mn, Ni, Pb, S, Ti, Zn, Zr and Au. Au was analysed by method Au-AA26 and the remaining elements by method ME-ICP61s.

Method Au-AA26: This is an ore grade technique using a 50gram charge with detection by fire assay with an AAS finish.

Method ME-ICP61s: uses a 4 acid digest of HF-HNO₃-HClO₄ acids with an HCl leach and inductively coupled plasma atomic emission spectrometry (ICP) detection.

The remainder of the drilling targeted the Ni mineralisation potential of the Cosmos Ultramafics. Samples were laid in 1m piles and sampled on nominal 1m (Vanguard) and 2m (Five Creeks, Cosmos West) composites by means of a poly spear. Samples were dispatched to ALS-Chemex laboratory in Perth for analysis of Ag, Al, As, Co, Cr, Cu, Fe, Mg, Mn, Ni, Pb, S, Ti, Zn, Zr and Au. Gold was analysed by method Au-AAS26 with the remaining elements being analysed by method ME-ICP61s (described previously).

Method Au-AA-26: Ore grade technique, which utilises a 50gram charge, assay by fire assay with an AAS finish.

Drill specifications are given in Table 13. Location plans are given in Figures 8 to 12 with cross sections given in Figures 13 to 29. Summary geology is given in Appendix 2 with summary assay data given in Appendix 3.

3.6.1 Vanguard

Target Drilling completed 16 holes (VSRC001-VSRC016) for 800m. All holes were drilled vertically to a depth of 50m for geotechnical and water level monitoring purposes, in order to evaluate the site for a portal access via underground decline to the Tapinos and Prospero nickel sulphide deposits on neighbouring tenure (reported under separate cover). The drilling was also sampled and analysed for gold and multi-elements.

The area is dominated by outcrop in 7 of the western holes and is overlain by transported cover in the east and south-east of the area. Depth of cover increases to 8m on the eastern side of the area, and a channel in the central south has a maximum depth of 13m in VSRC005. Depth to base of complete oxidation (BOCO) and top of fresh rock (TOF) also increases eastwards, away from the outcropping hill. No water aquifers were intersected and static ground water was minimal.

No anomalous Ni was intercepted within the drilling, best Cu results were:
 VSRC004 2m @ 1252 ppm Cu from 48m
 VSRC011 1m @ 1760ppm Cu from 44m

Low level gold anomalism between 0.1 and 0.2ppm Au was encountered in VSRC003, 6 and 8 with best intercept:

VSRC008 1m @ 0.92ppm Au from 44m

3.6.2 Ilias

Drilling was targeted at surface Au and As soil anomalies over this area. Previous RAB and RC drilling also returned sporadic anomalous intersections. Recent gravity and aeromagnetic data highlighted a shallow contact between the underlying basal ultramafics and the prospective Jones Creek Conglomerate. Mineralisation at Mossbecker and Yellow Aster occurs at, and adjacent to this contact and previous drilling had not adequately tested its potential at Ilias. The underlying ultramafics were also being tested for nickel geochemistry.

The conglomerate/ultramafic contact was intersected along the northern drill lines, with a dip ~45° W. The conglomerate is dominated by granitic

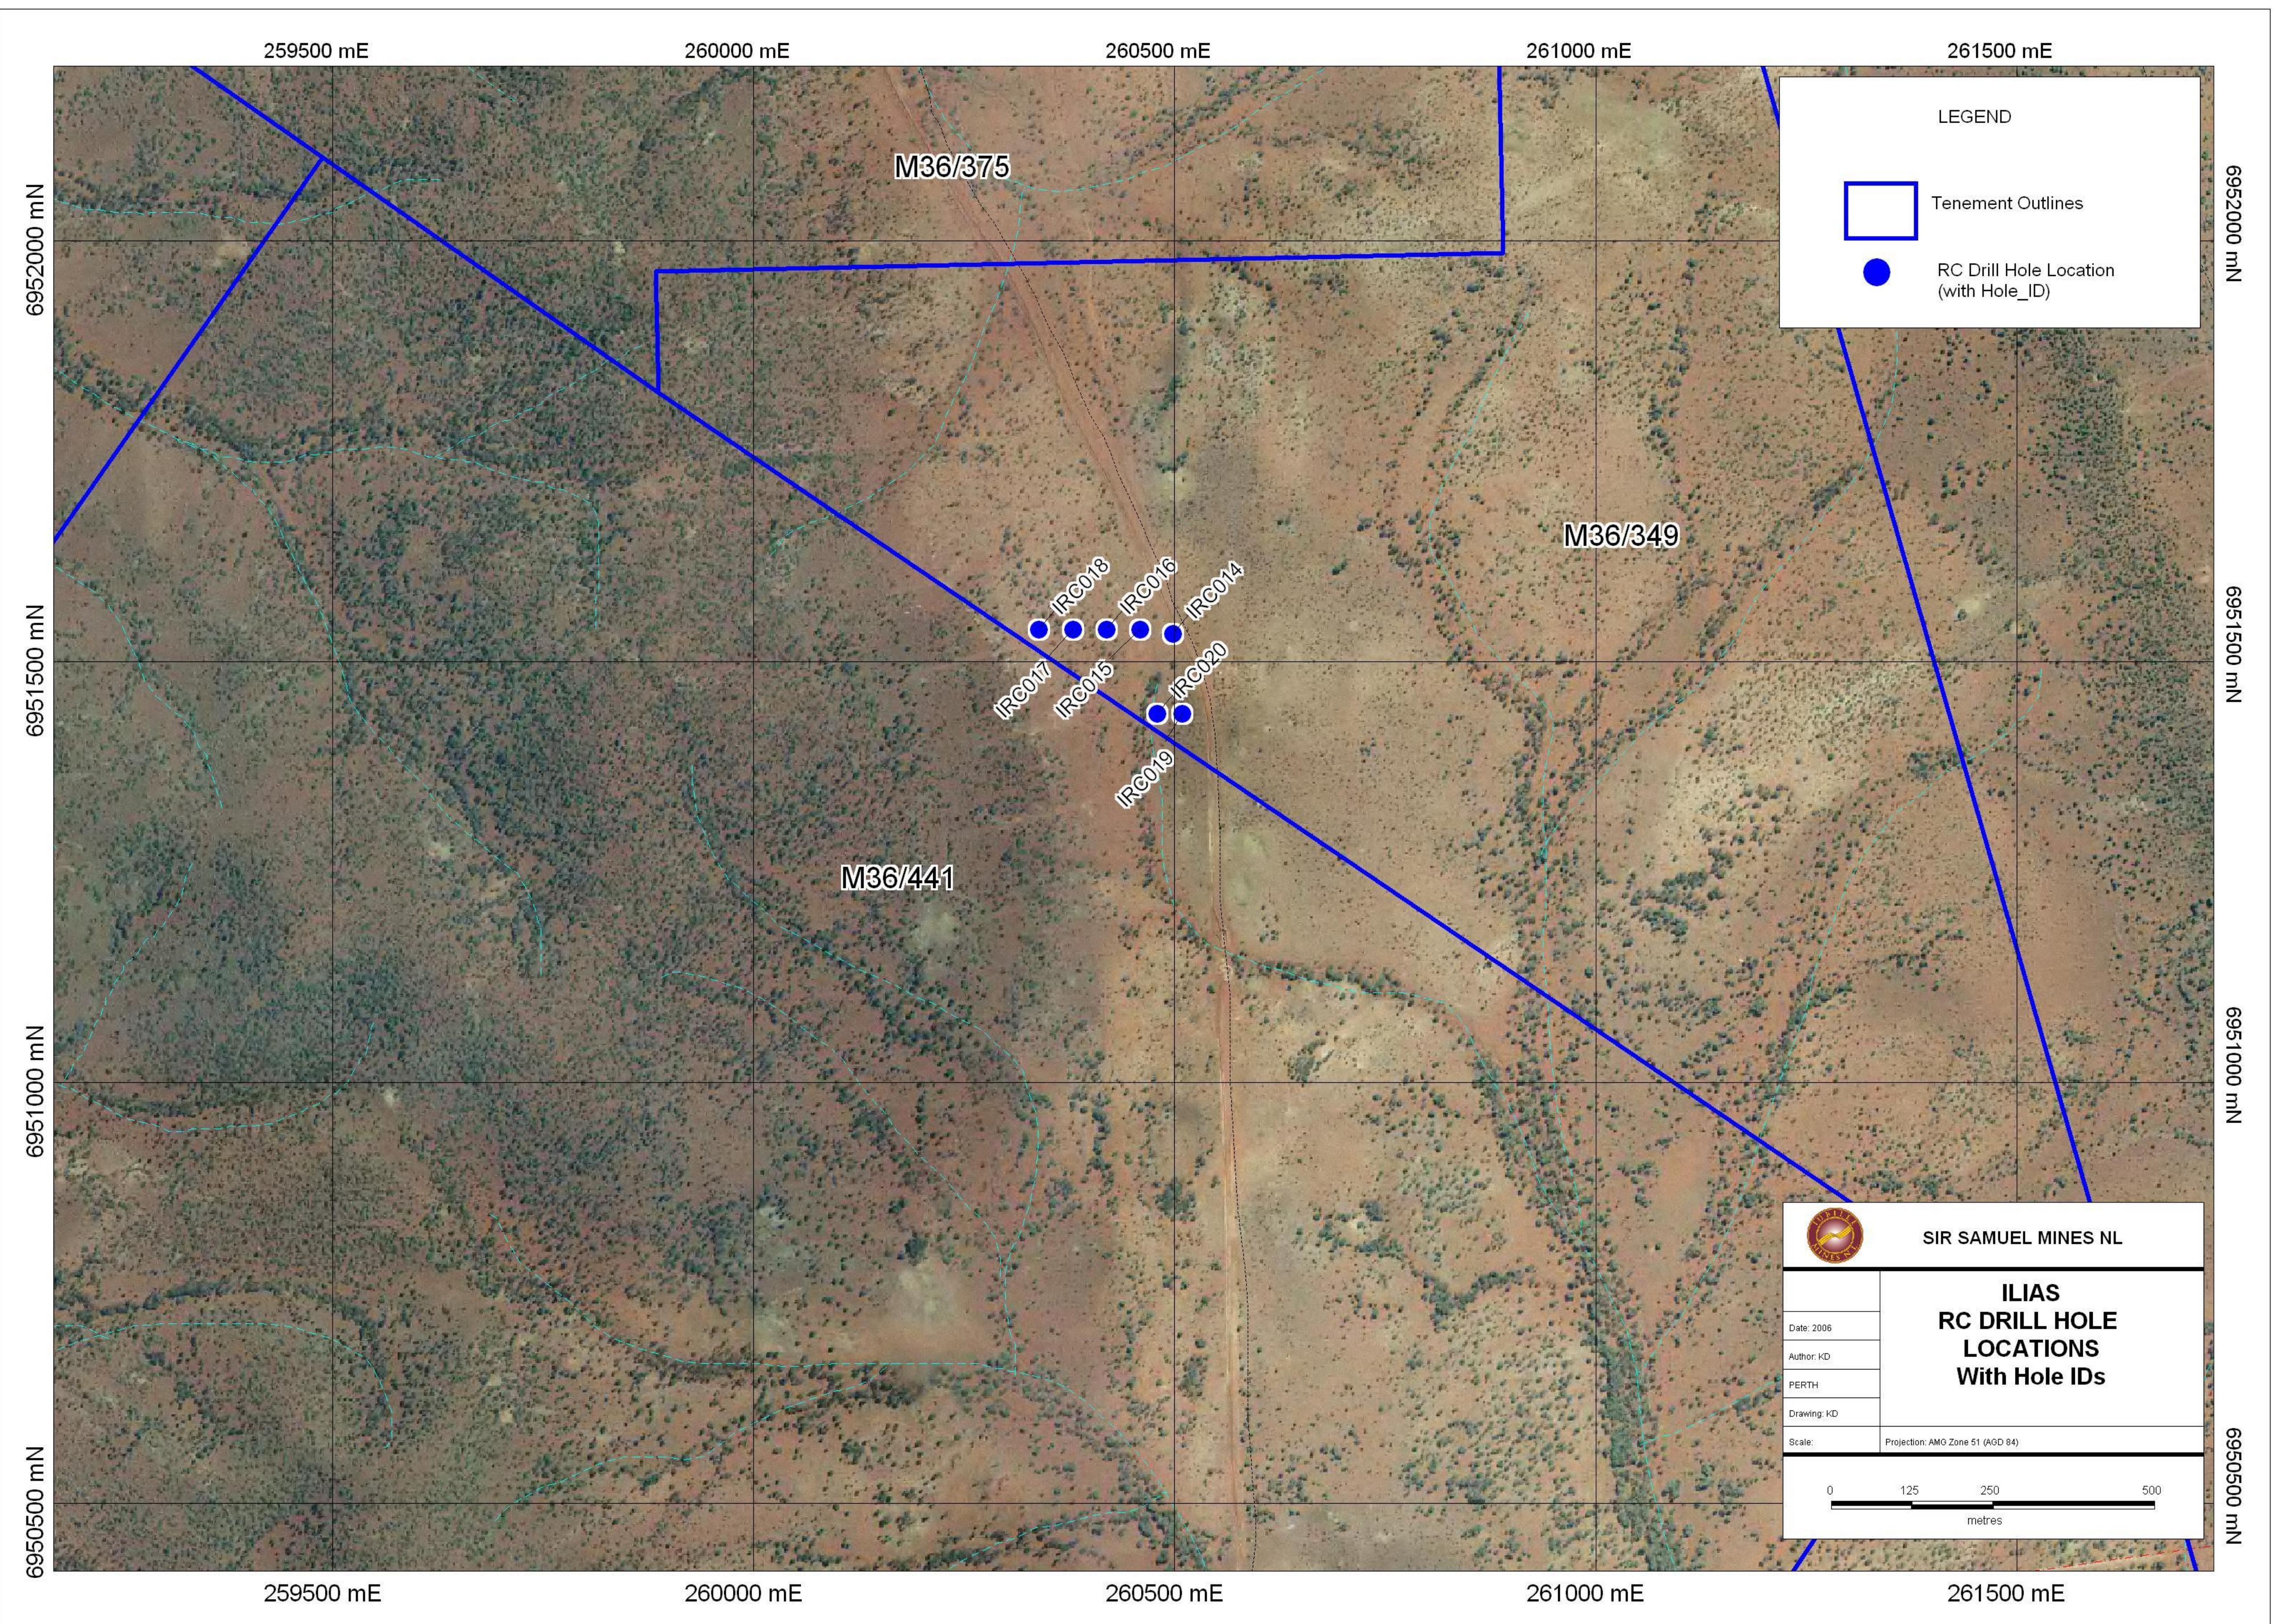

Figure 9

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

clasts with minor mafic clast rich zones, and is variably sericite altered, silicified and arsenopyrite + pyrite mineralised. The ultramafics are low MgO tremolite-chlorite and tremolite-actinolite rocks with variable talc and chlorite alteration. They are quite heavily quartz veined in zones and are generally pyrite mineralised with minor arsenopyrite.

Along the southern line (6951000N) the geology is more complex with low MgO tremolite-chlorite and tremolite-actinolite rocks forming the basal unit which is overlain by highly silicified mafic dominated conglomerate. This contact dips around 35-45° W and is approximately 33m thick at surface and thins to 12m thick down dip. It is overlain/over-thrust? by a higher MgO serpentised ultramafic wedge. At ~260425E a steeply west dipping fault occurs, bringing strongly sericite/epidote altered and arsenopyrite + pyrite mineralised granitic conglomerates into contact with the serpentised ultramafic wedge, the mafic conglomerate and the basal ultramafics. The granitic conglomerate is underlain by the same basal ultramafics, and is over-thrust to the west by basalts, along a 45° west dipping surface.

The results indicate a broad zone of low level gold mineralisation associated with alteration, but with only narrow sporadic higher grade results, see Table 14.

3.6.3 South Yellow Aster

A program of 2 angled RC holes (SYRC001-SYRC002) was completed at South Yellow Aster (278m). Drilling was designed to follow up previous intersection of 4.29g/t Au and 1.7g/t Au in vertical holes south of the Yellow Aster workings.

Drilling at South Yellow Aster intersected variably sericite altered, silicified and arsenopyrite mineralised granitic conglomerates. Low grade anomalous gold intersections are given in Table 15. Gold mineralisation is associated with elevated arsenic unlike that seen in the Ilias holes.

3.6.4 North Carriport

Drilling at North Carriport was aimed at following up historical results south of Yellow Aster and the un-drilled area between the Carriport workings to the south and the Yellow Aster workings to the north, in addition to a zone along the NW trending Hotel Fault immediately the north of Carriport.

The drilling intersected variably sericite altered, silicified and arsenopyrite mineralised granitic conglomerates. Anomalous gold intercepts are listed in Table 16, these holes returned higher grades than Ilias and North Yellow Aster but are again spotty, better grades in general correlate with elevated As >1000ppm.

3.6.5 Cosmos West

JVC025 and JVC026 were designed to test the western ultramafic contact below encouraging soil and rock chip geochemistry. Both holes were stopped prematurely due to drilling difficulties and require completion at a later date.

3.6.6 Five Creeks

A 10 hole reverse circulation program, FCC029-38, was completed to further test a number of targets believed to be prospective for extensions of the Yakabindie ultramafic sequence. No significant zones of mineralisation were intersected. No anomalous Ni intercepts were returned, two samples returned elevated gold:

FCC036 2m @ 390ppb Au from 40m in saprock over \$ UM

FCC038 2m @ 130ppb Au from 72m in interbedded black shale and \$ ultramafic.

3.7 *Diamond Drilling*

3.7.1 Vanguard-M36/24

Three holes were drilled at Vanguard, VSD002-5. VSD005 was drilled to gain geotechnical information on the decline path whilst VSD002 – VSD004 were designed to gain geotechnical information to aid in the design of the box cut for the portal development into the Prospero nickel sulphide deposit located on the adjoining tenure, M36/127, reported under separate cover.

Holes were drilled by contractor **Drillcorp Western Deep Hole** using a UDR1000 diamond rig. Holes were located on AMG grid by **Spectrum Surveys** using a DGPS.

Down hole surveys were carried out via a single shot **Eastman** camera for VSD002 with the remaining holes being surveyed by a north seeking gyro.

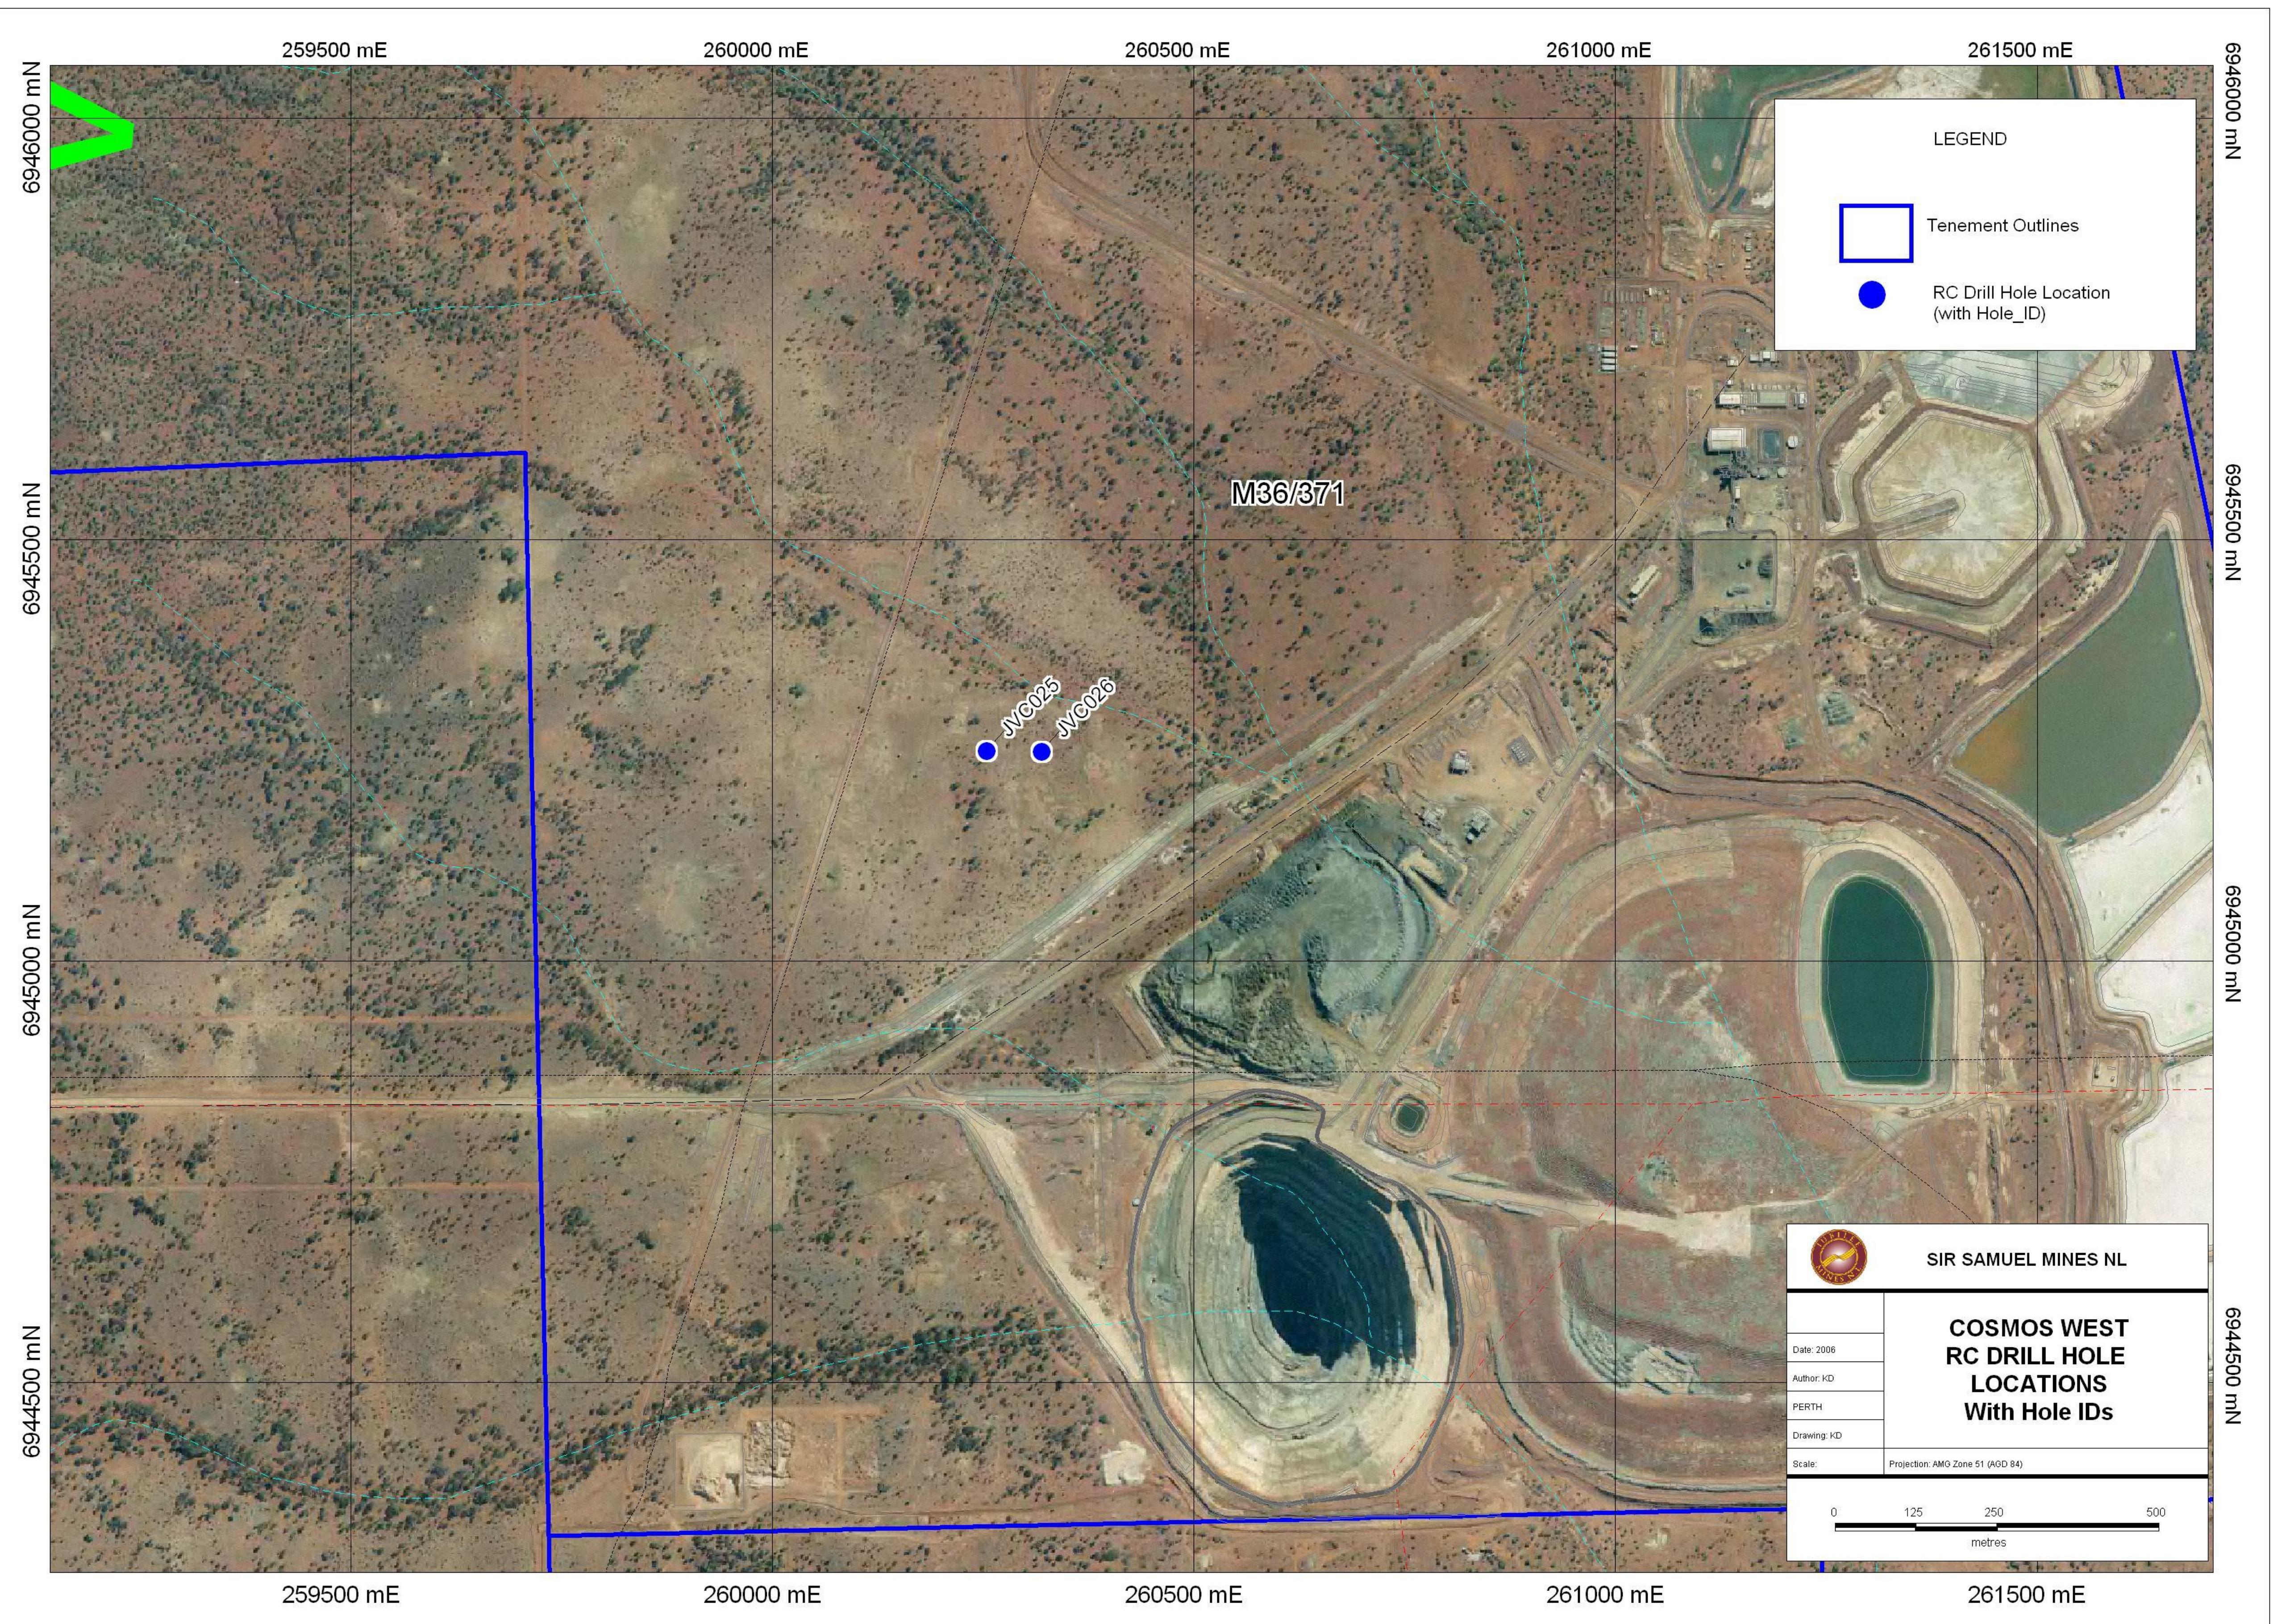

Figure 11

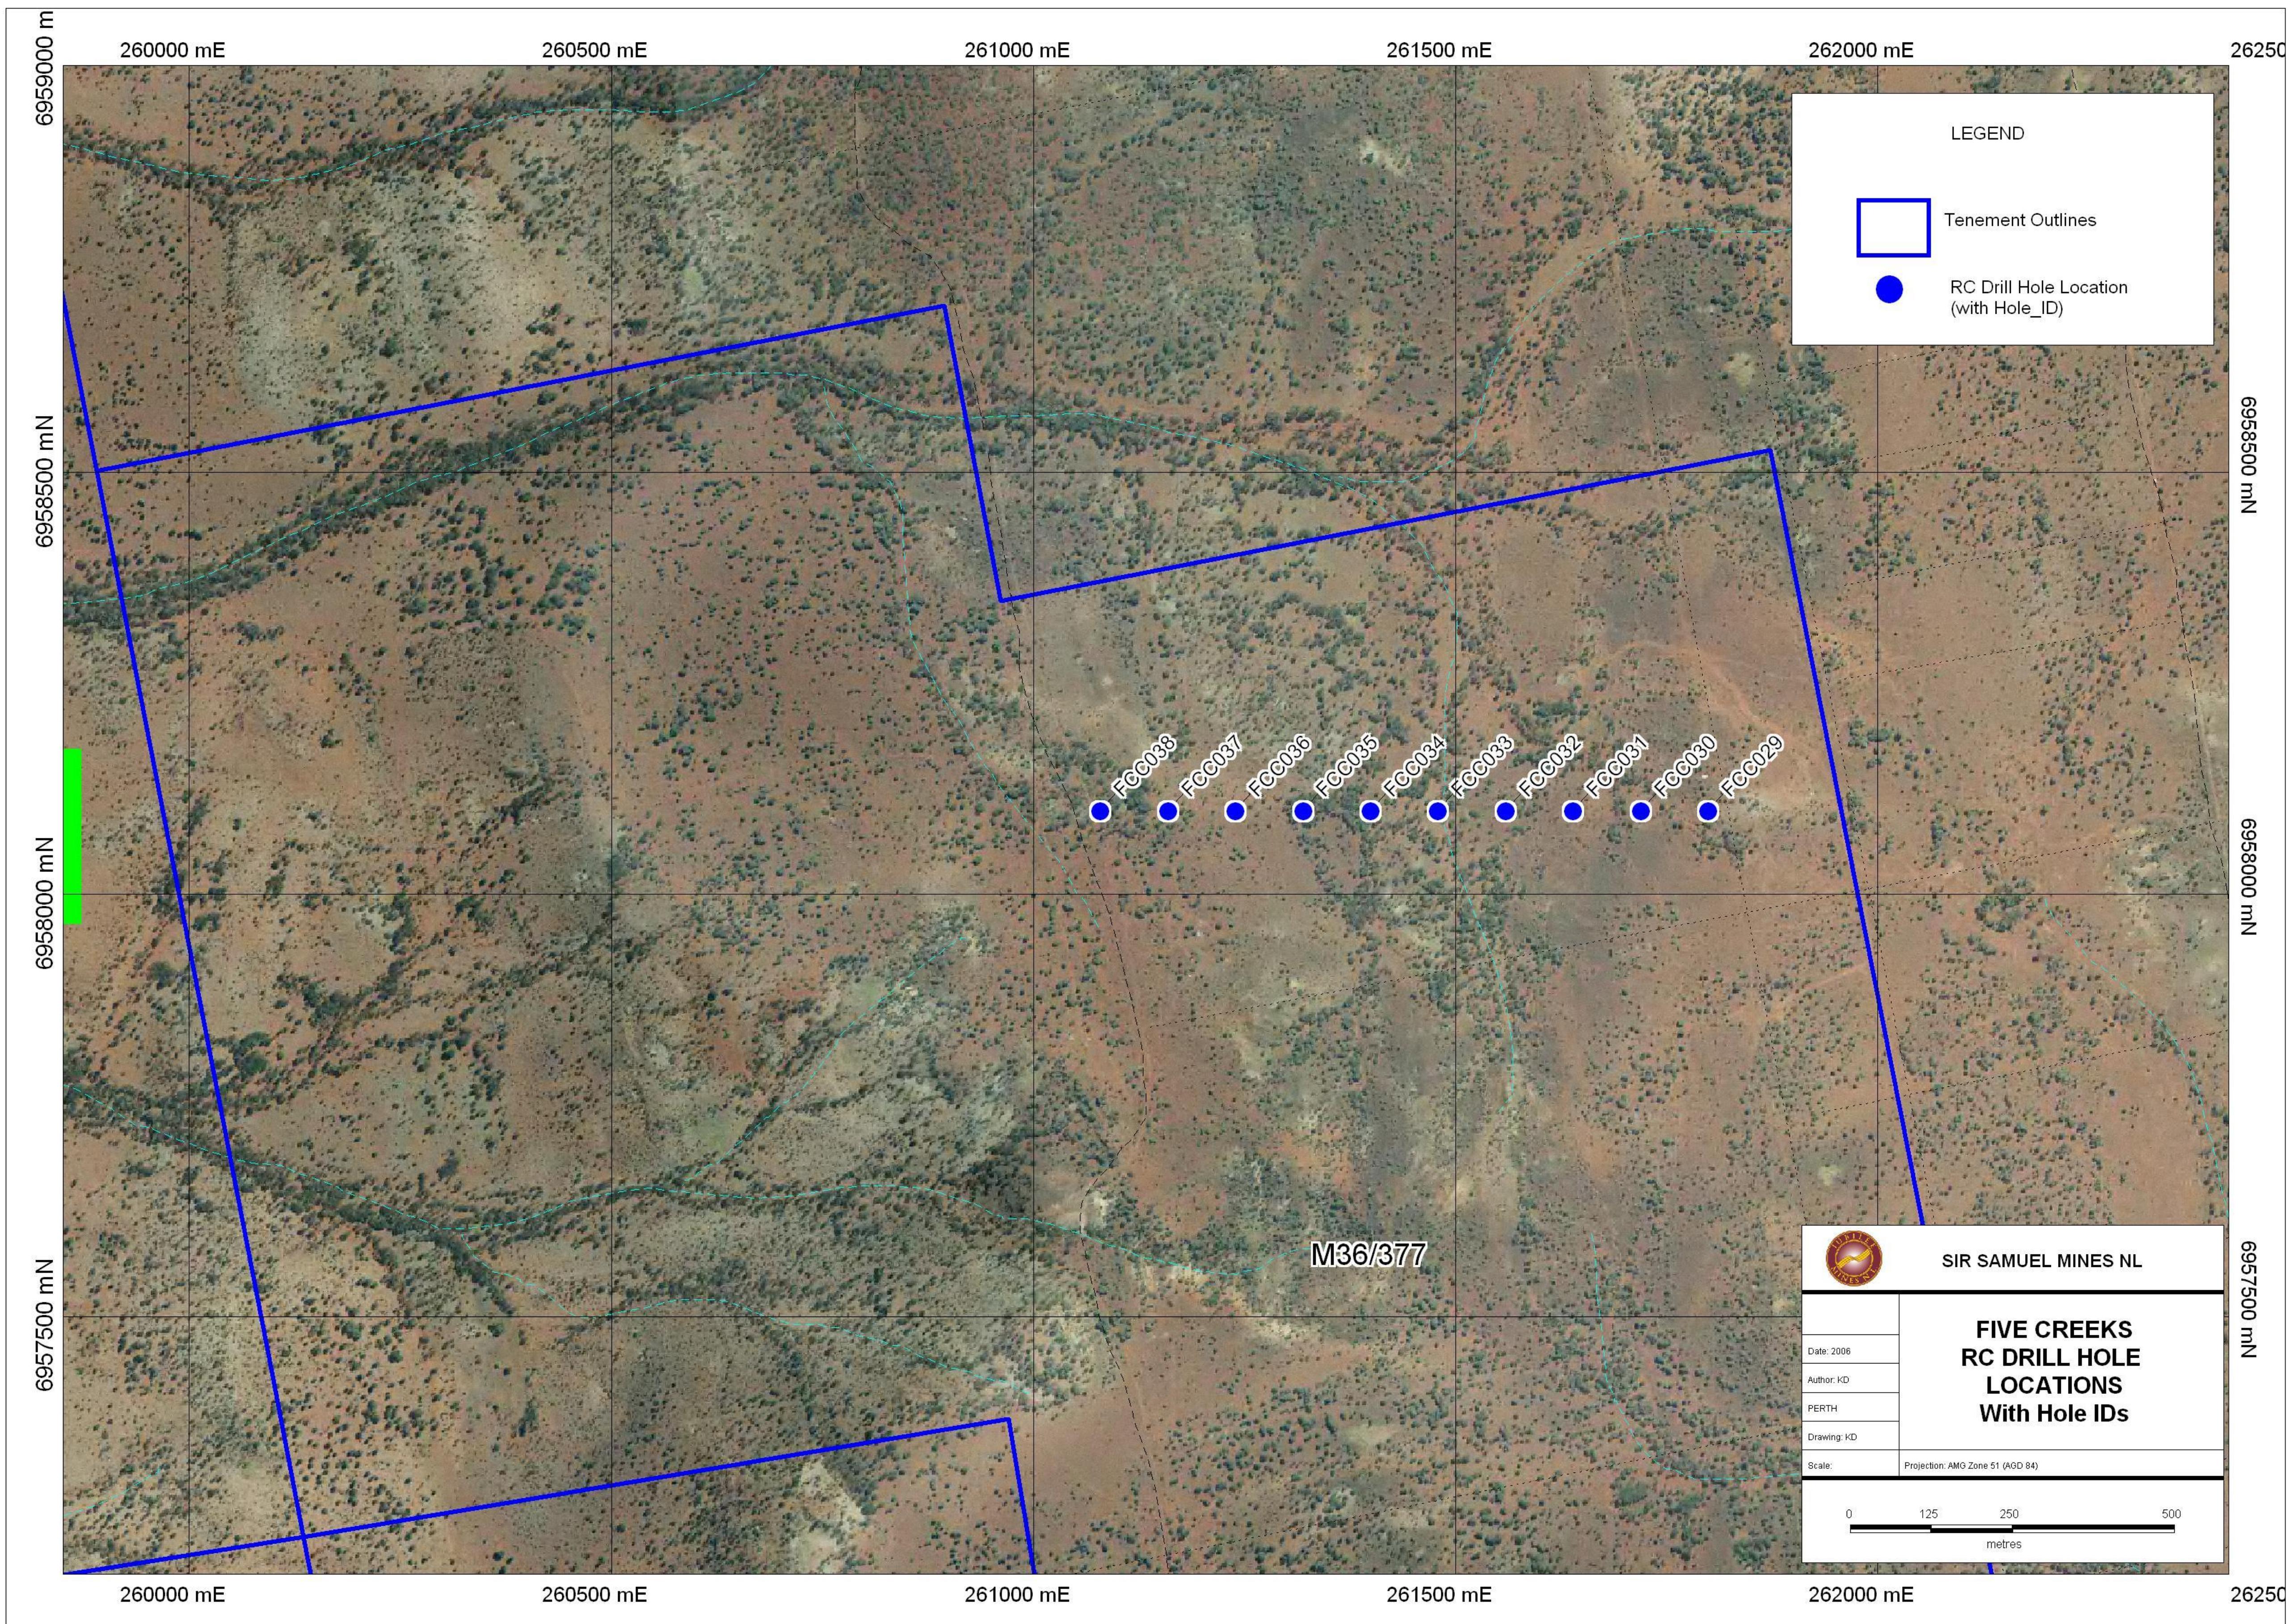

Figure 12

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

The diamond holes were advanced using an RC pre-collar and NQ2 diamond tail.

VSD005 diamond core was orientated via an **Ezymark** tool with core sawn in half. Half the core was sampled on nominal 1m intervals with closer intervals selected on geological interfaces in mineralised sections.

Samples were dispatched to **ALS-Chemex Laboratory** in Perth for analysis of Ag, Al, As, Co, Cr, Cu, Fe, Mg, Mn, Ni, Pb, S, Ti, Zn, Au, Pt and Pd. The PGE's were analysed by method **PGM-MS27**, the remaining elements were analysed by method **ME-ICP61**. Samples with Cu/Pb/Zn/Ag > 10000ppm were analysed by method **OG62**. **Method OG62** is an ore grade technique which utilises a three acid digest of HF-HNO₃-HCLO₄, with an ICP/AAS finish. The other methods have been described previously.

Drill Hole statistics are given in Table 17, anomalous base metals are given in Table 18. Drill hole locations are given in Figure 8, summary geology is given in Appendix 2, assay results are given in text files within the CD at the back of the report. Cross Sections are given in Figures 30 and 31.

Table17: Vanguard Diamond Drill Hole Statistics-M36/24

Hole ID	Prospect	Tenement	AMG East	AMG North	AMG RL	AMG Az 0°	Dip 0°	EOH Depth	No of Samples

VSD005	Vanguard	M36/24	259868.6	6941500	466.897	305	-75	190	13
Totals								335.6	13

The lithologies were predominantly basalt and dolerite, only VSD005 was assayed and returned anomalous base metals and gold associated with stringer and massive sulphide within andesites to a maximum of 0.9% Cu, 5.67 % Zn, 9.0% Pb and 0.73g/t Au, see Table 18 below, the mineralisation within a sulphidic intermediate volcanic pile is indicative of VMS mineralisation and should be investigated further.

3.7.2 Cosmos Deeps Underground Exploration-M36/371

A total of 41 underground exploration holes, CDE029-33, 037, 049-58, CME073-92 and ISD159-163 were drilled for a total of 7872.32m and 2316 Laboratory assay samples. The holes were drilled to define the basal contact to the Cosmos ultramafic in areas north, south and west of the existing underground operations. Drilling was carried out by contractor **Major Drilling Group Pty Ltd** using a Boart Longyear LMA 90 underground rig which was replaced during the program with a Boart Longyear LM75 underground rig. Drilling was advanced in NQ2/LTK60 sized core from underground stockpile locations.

Core was orientated via an **Ezymark** tool, sawn in half with half core dispatched to **Kalassay Laboratory** in Kalgoorlie where As, Ag, Mg, Cr, Fe, A, Mn, Al, Ti, Ni, Co, Cu, Zn and Pb were assayed using method ICP_14 which utilizes a four-acid digest with an ICPOES finish. Sampling was on nominal 1m intervals however in zones of mineralisation intervals were geologically determined. All drill hole co-ordinates are determined on the mine grid system which is a truncation of an AMG grid.

Drill Hole statistics are given in Table 19, anomalous intersections given in Table 20.

Western Ultramafic Limb

Stockpile 19 was refurbished for drill rig access to enable exploratory drilling to test the western limb of the UM and to identify possible down plunge, depth extensions of the Alec Mairs deposit. The western limb of the UM is now thought to be a faulted offset of the Cosmos UM which hosted the sulphides mined from the pit. It is regarded as having significant potential to host nickel sulphide mineralisation

CME073: This hole failed to intercept anomalous nickel.

Southern Ultramafic Exploration

CME074: This hole was drilled to test the continuity of the Cosmos Ultramafic south of existing reserves. CME074 intersected a narrow zone of stringer mineralization in Felsic Volcanics at 80.74 – 81.30m, and several zones of disseminated to stringer mineralization at 99.42 – 99.55m, 100.15 – 100.46m(**0.31m @ 1.21% Ni**), and 101.22 – 102.77m(best of **0.19m @ 2.51% Ni**).

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

CME075 intersected several narrow zones of stringer mineralization in Felsic Volcanics at 56.83 – 57.05m, 105.70 – 106.22m, and 109.11 – 109.48m (0.37m @ 0.62% Ni).

CME076 intersected a narrow zone of stringer mineralization at 85.36 – 86.20m.

CME077 intersected a zone of massive ore at 108.60 – 108.70m (**0.1m @ 13.4% Ni**) with several intersections of disseminated to stringer mineralization both up and down hole from the massive ore.

CME078 was drilled successfully with no significant intersections recorded.

CME079 intersected cm scaled pentlandite phenocrysts densely scattered throughout an interval, 97.91-98.76m (**0.85m @ 12.54% Ni**) whilst at 98.76-101.28m (**best of 0.74m @ 4.7% Ni, 1m @ 5.17% Ni and 0.78m @ 4.9% Ni**) breccia sulphide was intersected.

CME080 intersected 1cm stringer sulphide at 87.2m and blebby pyrite throughout 85.26-90.7m. A 0.6m sample of ultramafic at end of hole returned a nickel value of 1.07%, unfortunately the hole was abandoned due to hole collapse and bad ground conditions.

CME081 returned narrow zones of breccia and stringer sulphides at 37.11-38.11m with a zone of disseminated blebby mineralisation at 44.4-45.19m, massive sulphide at 108.5-108.65m returned **0.15m @ 6.94% Ni**.

CME082 intersected four intervals of breccia sulphides, the most significant being 70.94-71.08m, 71.12-71.27m which returned 40% sulphides (**0.15m @ 5.71% Ni**) with the other 3 returning around 5% sulphides at:

72.30-72.34m

77.16-77.53m

77.8-78.2m

The ultramafic contact was intersected at 80.76m

CME083 intersected semi-massive sulphides at 75.71m within an ultramafic breccia zone which returned:

0.43m @ 18.3% Ni from 75.71m, other intercepts returned:

0.51m @ 3.51% Ni from 71.88m

1.03m @ 2.85% Ni from 119.42m

CME090 intersected three zones of semi massive sulphides:

54.35-54.55m has 10% sulphides, **0.1m @ 5.02% Ni**.

54.86-55.08m has 2% sulphides with chalcopyrite stringers

55.55-56.09m has 5% stringer in intermediate volcanics, returning **0.54m @ 3.98% Ni**.

CME091 intersected the ultramafic contact at 111.48m without intersecting mineralisation.

CME092 intersected the ultramafic contact at 136.47m without intersecting mineralisation.

Northern Ultramafic Exploration

CME084 intersected the ultramafic boundary at 148.46m with the unit extending to 173.35m where a siliceous boundary was seen with the Quartz Feldspar Porphyry.

CME085 intersected the ultramafic unit from 162.19m to 180.13m followed by the Quartz Feldspar Porphyry. Pyrite and Pyrrhotite stringers in Garnetiferous Felsic Volcanics were intersected at 39.07 – 39.28m. In addition, scattered blebs of sulphide mineralization were found in Felsic Volcanics at 142.09 – 142.20m and 143.9 – 144.22m. Results are pending.

CME086 intersected narrow zones of disseminated sulphides in Felsic Volcanics at 18.92 – 19.14m, 41.55 – 41.7m and 54.0 – 58.22m. The Ultramafic unit extended from 147.08m until the contact with the Felsic Porphyry at 166.87m.

CME087 intersected highly altered Ultramafics from 167.33 – 171.63m. A serpentine altered Quartz Feldspar Porphyry continued from 171.63m to EOH.

CME088 intersected the ultramafic contact at 145.68, whilst **CME 089** intersected the same contact at 151.44m however no mineralisation was present in either hole.

A geotechnical hole, **CDE030** was also drilled along the proposed Alec Mairs Decline 2 path.

ISD159 to ISD163 were drilled from the 9920 level testing the hanging wall position of Main Lode on the 9895 lift 3 level (above the current level). Mining of the 9895 lift 2 level indicated that the mineralization did not continue up into the next lift as no ore was present in either the backs or western wall. These drill holes confirmed that this portion of the ore body has been closed off. A very narrow zone of mineralization was intersected in ISD159 close to the collar (which represents a stringer visible on 9920), but no mineralization was intersected in any of the holes at the target depths.

Cosmos Deeps Continuity of Mineralisation Drilling

This drilling from stockpile 16 tested the continuity of mineralisation between the pit and the underground mineralisation in addition to

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

confirming the position of the ultramafic. Holes CDE049-57 tested this zone.

CDE049 intersected stringer mineralisation in Felsic volcanics at 140.6-140.7m at 0.08% Ni, the ultramafic was intersected at 145.61m.

CDE050 did not intersect any mineralisation within felsic or ultramafics which was intersected at 178.07m.

CDE051-57 nothing significant was returned from these holes.

UP Plunge Position of Main Lode Drilling

Drilling from stockpile 18 was designed to test the up plunge position of the Main Lode. Holes CDE031-33 and CDE037 tested this zone.

CDE031 intersected breccia sulphides in garnetiferous felsic volcanics at 174.46m and 296.24m. Ultramafic rocks were intersected within the Felsic Volcanics at two intervals. A highly fractured and brecciated fault zone at 183.1 – 83.72m consisted of Felsic Volcanics and Ultramafic Chlorite Schist. A zone of Ultramafic Tremolite Actinolite rock with sheared Biotite-rich boundaries was intersected at 193.67 – 194.9m. Following a zone of Felsic Volcanics, the ultramafic sequence was found to be 80m thick from 226.3m to where it contacted the Felsic Porphyry at 306.15m.

CDE032: A zone of Intermediate Volcanics from 192.8 - 204m included several small intervals approximately 30cm each of patchy Semi-massive sulphides. Results are pending. A thin intersection of Ultramafics within the Fv occurred at 212.99 – 213.47m with the main body of Ultramafics at a thickness of 69m from 236.23m to the contact with the Felsic Porphyry at 305.16m.

CDE033 did not intersect any mineralisation.

CDE037: With the exception of trace sulphides, no significant mineralization was identified. Approximately 80m of ultramafic sequence was intersected at 206.73m extending to 288.20m, where a fractured zone of Felsic Porphyry was encountered. The Felsic Porphyry, strongly serpentine-altered with quartz veining, continued for 13.2m to end of hole.

Other Underground Drilling

CDE058 was drilled as a cover hole from Stockpile 3 to test for water and gas and to test ground conditions. Water was intersected at 108.4m producing some 15 litres/minute coinciding with friable, talc altered quartz veining in felsic volcanics. No ultramafic or gas were intercepted.

3.8 Geophysics

3.8.1 Mercury-Venus- MLEM Survey-M36/371

Contractor **Fugro Ground Geophysics (Fugro)** carried out surface EM over prospect areas Mercury-Venus to better define and infill previous surveys. A total of 23 lines for 27.8line km and 583 stations were completed. The data was interpreted by consultant **Southern Geoscience Consultants (SGC)**. Survey details are given below with survey locations given in Table 21 and shown in Figure1. Model Images are given in Appendix 3.

Contractor:	Fugro Ground Geophysics	Channels: up to 36
Receiver:	SmarTEM	(2Hz)
		Current: approx
Transmitter:	Zonge ZT-30	20Amps
Sensors:	Bartington Fluxgate Magnetometer, RVR coil.	
Arrays:	In-loop ±slingram, 100m x 100m, triple turn

			<u>27.80</u>	<u>583</u>
23 lines, 27.8km, 583stations				

The C₈ and C₁₁ anomalies defined previously were confirmed from this survey, one new discrete anomaly was defined in an area not previously surveyed. The anomaly is centred on ~259050mE/6945700mN coincident with a magnetic high and trending NW within meta volcanics. It has similar characteristics to the Stellar MLEM anomaly which when drilled proved to be pyrrhotite within sediments. This new conductor may prove to be a VMS target as well. Modeling suggests the conductor is small, 250m by 50m, shallow ~50m depth with a steep ENE dip; it could be tested via in-fill FLEM or an RC hole as follows:

Hole drilled at 259110mE/6945700mN, Azimuth 270⁰, dip -60⁰ with an intersection depth of ~85m and max depth ~ 125m would test the conductor.

At the time of writing this report detailed interpretation of this data has not been completed by *SGC*.

3.8.2 Five Creeks-BHPB Geoferret MLEM Survey-M36/377

During the period BHP Billiton requested permission to place surface EM loops within M36/377 (Five Creeks). JBM gave permission and BHP Billiton supplied JBM with only that data within M36/377. Survey specifications are given below with images given in Appendix 3.

Acquisition:	WMC / BHP Billiton
Survey Date:	August 2005
Configuration:	FLEM
Transmitter:	GGT-30
Receiver:	Geoferret Coil
Loop Size:	1000x500m x 2 turns
Current:	36Amp (effective?)
Base Frequency:	0.27778Hz
Sample Rate / Stacks:	25000 / 100
Ramp:	600usec
Coordinate System:	Local Six Mile Grid
Loop Corners:	9750-10250E, 13400-14400N
15 survey lines:	each 250m long = 3.75line km
Readings:	every 50m = 87 stations.

No anomalies were defined within the JBM ground.

3.8.3 Downhole EM

Downhole EM (DHEM) was carried out both on surface holes and underground holes by contractor **Outer Rim Exploration (ORE)** under the guidance of **SGC** details are given below:

Contractor:	Outer Rim Exploration Services
Time Base:	50ms
Ramp Time:	1.50ms
Channels:	36
Current:	30-40 amps
Instrument:	Crone PEM
Receiver:	Digital #126
Readings:	10m intervals 2-5m over anomalies

3.8.3.1 Vanguard

One geotech hole, VSD005 was surveyed, this hole intersected massive sulphide ~182m which returned 9% Zn. Unfortunately the hole was blocked beyond 183m, the area of interest.

Overall the dataset is relatively flat (before the noise starts) with no sign of any significant off-hole conductors. There is a small anomaly in the very last reading which is consistent with the massive sulphide intersected ~182m However, there is nothing in the data to suggest the zone gets any thicker near this hole. The results have therefore downgraded the potential of this target.

3.8.3.2 Underground

Details of the underground DHEM results are given in Table 22; loop sizes were 400 by 400m-double turn or 400 by 700m-double turn. Modelled conductors are given in Appendix 3.

Table 22: Summary DHEM-Cosmos Underground

Hole	Depth of	Anomaly	Modelled	Comments
ID	Anomaly (m)	Type	Parameters	
CME073	#~190m	#off-hole complex		# Adjacent to UM/felsic contact
	#~230m	# Off-hole in XY, single spike in Z		Poss sub-parallel to hole
	# ~290m	Y only		#Expected to be Current Channelling

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

4 Mining

Mining progressed at Cosmos Deeps with production statistics given in Table 25, mine development is given in Figure 32. Ore was dispatched to Inco Smelter in Canada; details of the shipments are given in Table 26. Underground mining is carried out by contractors, **Byrncut Mining**, using long-hole stoping and cut and fill methods in the following areas:

March Q: 895 Cut, 970 B lode, 920 C lode

June Q: 9895, 9870, 9970 B Lode, 9945 N & S Stopes

September Q: Central Portion of the Deeps

December Q: Central Portion of the Deeps

Table 25: Cosmos Production Statistics-2005

	March 05 Q	June 05 Q	Sept 05 Q	Dec 05 Q	Project to Date
Ore Mined (tonnes)	54,180.00	53,664.00	55,361.00	32,720.00	847,896.00

4.1 Cosmos Deeps Reserve

The Cosmos Deeps reserve was derived from a grade control model as at June 2005 interrogated against life of mine design. Estimation of the ore reserve utilises a 1.4% block cut-off.

Table 27: Cosmos Deeps Resource
(With depletion by production as at June 2005)

Appendix 1

SOIL SAMPLING PROTOCOLS

Sample Site Selection

A sample site should represent the typicality of the immediate area. Avoid the abnormal.

Sample Details

At each site record coordinates and the soil details as per project requirements (see Snr Exploration Geologist and DET soil.xls).

Sample Site Preparation

1. Scrape over an area of approx 1m diameter to remove surface crust, surface lag & vegetation.
ENSURE NO SURFACE CONTAMINATION.
2. Dig over and mix very well (homogenization) the central 30-40cm of the cleared area to a depth of approx 25cm. **DO NOT DIG DEEPER HOLES**

Sample Collection

- Scoop sample from 5 to 25 cm depth. **DO NOT SAMPLE DEEPER.**

Sample Sieving

- Dry sieve at the sample site to collect ~100 gms of -250um sample.
- After sampling fill the hole and level the area sampled.

Field Duplicates

Select a representative site within~1-2m of the original site and sample as described above. **DO NOT** collect duplicate sample from the original hole. Collect at a rate of 4:100 and consecutively number after the original sample number (i.e. 00/01, 24/25, 49/50, 74/75).

Certified Reference Materials (CRMs)

Add 35-50 g of CRM into a Kraft sample bags at a rate of 4 in 100 (i.e. sample number 10, 35, 60, and 85).

		L	Low
		M	Medium

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

	H	High
	VH	Very High
	EH	Extremely High
Reference_Line	BOC	Bottom of Core
	TOC	Top of Core

Roughness

Column Name	Group	Code	Description
Roughness	N/A	1	Stepped: Rough
		2	Stepped: Smooth
		3	Stepped: Slickensided
		4	Undulating: Rough
		5	Undulating: Smooth
		6	Undulating: Slickensided
		7	Planar: Rough
		8	Planar: Smooth
		9	Planar: Slickensided

Infill - See Geology Codes: Lithology, Mineralogy Codes: Mineral.

Surface Sampling

Surface Sampling DET's (One for Rock samples, one for soil samples)

FOR BOTH SAMPLE TYPES:

Grid_ID will usually be AMG84_51

Column Name	Code	Description
SampleType	Gossan	Rockchip sample of a Gossan
(In the manual form, this is stated in the Header info!)	LAG	LAG sample
	Rock	Rockchip Sample
	Soil	Soil Sample
	Stream	Stream Sediment sample
Sample_Category	2C	Two point composite soil sample
	3C	Three point composite soil sample
	SG	Single point Gossan chip sample
	SR	Single point rockchip sample
	SL	Single point LAG sample

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

	ST	Single Point Stream Sediment sample
	DUP	Duplicate Sample
	STD	Standard inserted
Survey_Method	DGPS	Located using Differential GPS
(In the manual form, this is stated in the Header info!)	EST	Estimated Location
	GPS	Located using GPS
	NOM	Nominal point location
	SURV	Surveyed Location
	UNKN	Unknown Survey Method

SPECIFIC SOIL SAMPLING CODES

Weight is stated in GRAMS

Mesh Size will usually be -250um

Column Name	Code	Description
Origin (Lith_1 in database)	TA	Alluvial Soil
	TC	Colluvial Soil
	TE	Aeolian Soil
	R	Residual Soil
	TI	Indeterminant Soil
Mineralogy (Lith_2 in Database)	Cca	Calcareous
	Cfe	Ferruginous
	Ccz	Clay
	Cmn	Manganiferous
	Csi	Silica rich
	Cti	Indeterminant
Grainsize	L	Loam, (<250um)
	S	Sand, (250um to 2.00mm)
	G	Gravels, (>2.00mm)
Surface	C	Subcrop
	O	Outcrop
	S	Soil
	X	Indeterminant
Slope	F	Flat (0-5)
	G	Gentle (5-15)
	M	Moderate (15-25)
	S	Steep (>25)
Terrain	A	Agriculture
	I	Infrastructure
	M	Mining
	N	Natural

Jubilee Mines NL-Kathleen Valley Project- Technical Report No 733

Vegetation	Y	Yes, vegetation within 1-2m
	N	No, no vegetation within 1-2m

SPECIFIC ROCKCHIP SAMPLING CODES

The codes for the COLOUR, LITH, TEXT, MIN and ALT columns can be found in the previous tabs of this dictionary!

Colour, Lithology and Texture codes are found in "Geology Codes"

Mineralogy codes are found in the tab of the same name.

Alteration Codes as above.

Appendix 2

Soil Sample Locations & Assay Results

See pdf file on CD in Back Pocket of Report
