

# 142902: foliated biotite monzogranite dyke, No. 2 Bore

## Location and sampling

ROBINSON RANGE (SG 50-7)

Sampled on 8 October 1997

AMG Zone 50, 544070E 7170960N

The sample was taken from a 5 m diameter, 1 m high whaleback located about 50 m south of the site of sample 142901, 300 m south of a fence and about 2 km east of No. 2 Bore.

## Tectonic unit/relations

This sample is of a weakly foliated even, medium-grained biotite monzogranite. This is interlayered with, and has been intruded by, veins of a foliated sparsely porphyritic biotite monzogranite, of which sample 142901 is representative.

## Petrographic description

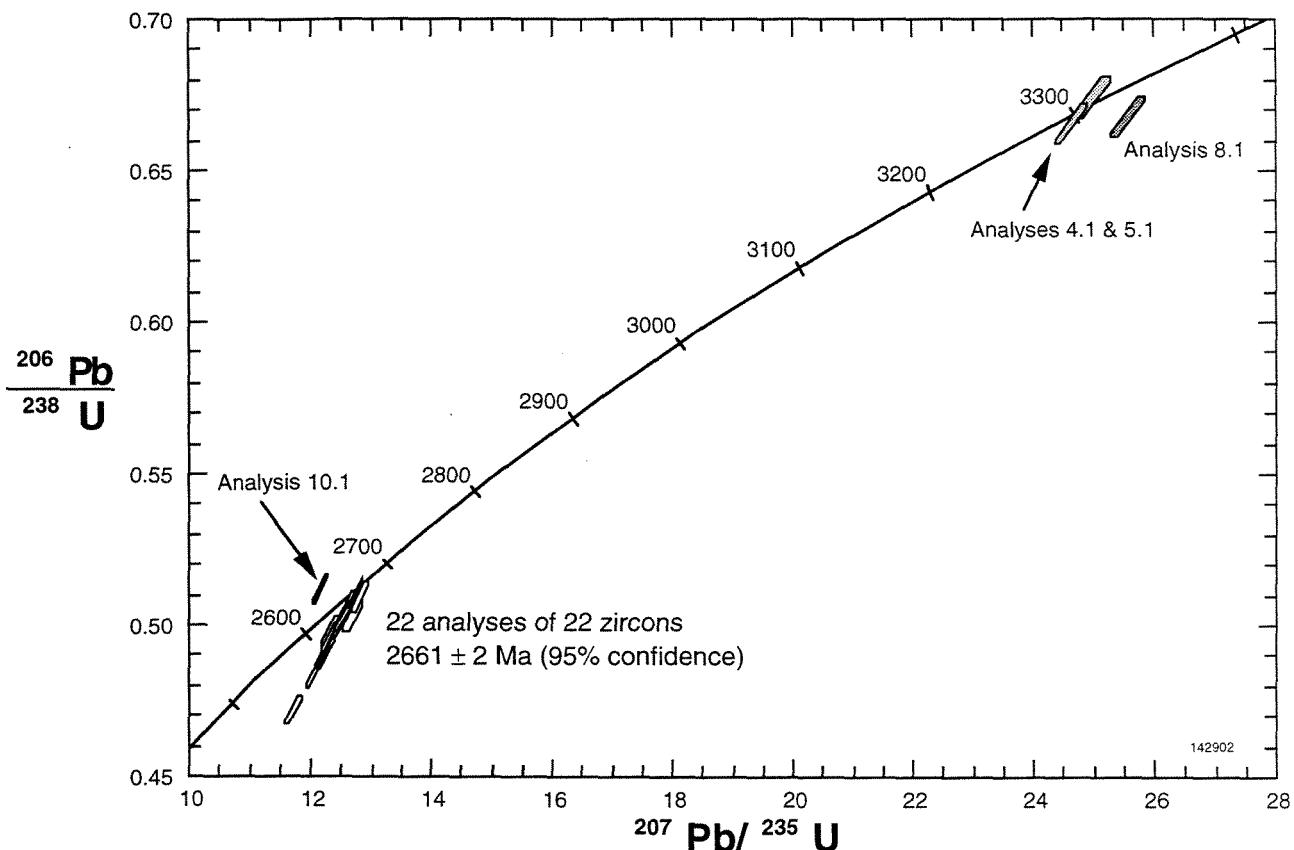

The major minerals present in this sample are plagioclase (30 vol. %), microcline (43 vol. %), quartz (25 vol. %), biotite (2 vol. %) and myrmekite. Plagioclase is irregular in grain shape and ranges from coarse grained to fine or medium grained. The plagioclase is probably oligoclase, or albite degraded from oligoclase, but its composition was not directly determined. It has been heavily saussuritized. Microcline also has a bimodal grain size distribution, coarse and fine. Grain shape is irregular to round. Biotite is evenly distributed in grains that are variable in size within the finer size classes. There is some myrmekite. Accessory minerals include opaque grains, apatite, possible metamict allanite, and zircon. Secondary minerals include epidote, mainly associated with biotite. Epidote also occurs with sericite as saussurite in plagioclase. Chlorite is rare. The rock has a bimodal texture with coarse grains sitting in a fine groundmass. There may be some weak foliation. Coarse feldspar grains are porphyroclasts whereas the fine feldspar and much of the quartz has been recrystallized from a poorly developed mortar. The mortar developed probably during dynamothermal metamorphism. This rock is a lightly deformed and metamorphosed biotite monzogranite.

## Zircon morphology

The zircons extracted from this sample are generally euhedral to rounded in shape, straw-brown, dark-brown or black in colour, and are typically  $100 \times 150 \mu\text{m}$  but range up to  $400 \times 250 \mu\text{m}$  in size. Many show euhedral internal zonation, are mottled, and have dark cracks, suggesting extensive internal recrystallization.

## Analytical details

This sample was analysed on 8 December 1997. The counter deadtime was 32 ns. Eight analyses of the CZ3 standard obtained during the analysis session indicated a  $\text{Pb}^*/\text{U}$  calibration error of 0.939 ( $1\sigma\%$ ). Common-Pb corrections were made assuming Broken Hill common Pb for all unknown analyses with the exception of analyses 4.1, 11.1, 12.1, 14.1, 15.1, 19.1, 21.1 and 26.1, for which Pb isotopic compositions determined using the method of Cumming and Richards (1975) were assumed.

**Figure 66. Concordia plot for sample 142902: foliated biotite monzogranite dyke, No. 2 Bore**

## Results

Twenty-six analyses were obtained from 26 zircons. Results are given in Table 65 and shown on a concordia plot in Figure 66.

## Interpretation

Twenty-two concordant and variably discordant analyses of 22 zircons (1.1, 2.1, 5.1, 6.1, 7.1, 10.1, 11.1, 12.1, 13.1, 14.1, 15.1, 19.1, 20.1, 23.1, 24.1, 25.1 and 26.1) have a weighted mean  $^{207}\text{Pb}/^{206}\text{Pb}$  ratio corresponding to a date of  $2661 \pm 2$  Ma (chi-squared = 1.68). This date is interpreted to provide the time of igneous crystallization of the granite dyke. Analyses 4.1, 5.1 and 8.1 indicate significantly higher  $^{207}\text{Pb}/^{206}\text{Pb}$  ratios and are interpreted to be of xenocryst zircons. Reversely discordant analysis 10.1 indicates a lower  $^{207}\text{Pb}/^{206}\text{Pb}$  ratio and the radiogenic Pb at this analysis site is interpreted to have undergone some redistribution.
